## 1. GENERAL

1.01 This section describes the procedures and methods for computing the Load Balance Index (LBI) for No. 1 and 1A ESS switches.
1.02 This section is being reissued to delete references to manual load balance procedures and forms. The procedure for reporting of the LBI to American Telephone and Telegraph (AT\&T) is also eliminated with this issue. Additional revisions to this section include deletion of information that is common to all switching systems. This information is now included in Section 780-350-050. This section provides a new index table that more accurately provides a relationship between the LBI and the grade of service being provided by the switching machine. Further highlighting of poor service is provided by a

NOTICE
Not for use or disclosure outside the
special "hot spot" classification. A load unit is labeled a "hot spot" when its 10 hour weekly average load, for load balancing, exceeds a predetermined threshold value. The threshold values are provided later in this section.

## 2. LOADING CONSIDERATIONS LOAD UNIT CONFIGURATION

## LOAD UNIT CONFIGURATION

2.01 The load unit in a No. 1/1A ESS switch is the concentrator. A concentrator consists of two stages of switching that concentrate and distribute the traffic over various paths. Two levels of concentration (ie, 2:1 and 4:1) can be provided in No. 1/1A ESS switches.
2.02 The $2: 1$ concentrator serves up to 32 customers. As the following illustration shows, these 32 customers have access to 16 B-links. Each concentrator contains eight 4 -by- 4 stage 0 switches and four 8 -by-4 stage 1 switches. Stage 0 switches do not provide any concentration and are used only to distribute traffic over the stage 1 switches. Stage 1 switches provide the $2: 1$ concentration and distribute the traffic over the 16 B-links. The B-links, in turn, are distributed in a patterned manner over the line junctor switch frames within the network. No concentration occurs in the line junctor switch frames.

2.03 The basic measured balancing unit is a concentrator. However switch balance in a $2: 1$ network is important. Although concentration does not occur in stage 0 , class-of-service distribution by switch within a concentrator is necessary. Large numbers of the same class of service in one switch will increase the probability of blocked dial tone. Further blockage can also occur in stage 1 or at the B-links.
2.04 The 4:1 concentrator serves up to 64 customers. The following illustration shows how these customers access the 16 available B-links. Each concentrator contains four 16 -by- 8 stage 0 switches and four 8 -by- 4 stage 1 switches. Stage 0 switches perform a $2: 1$ concentration function and distribute the 32 paths over the stage 1 switches. Stage 1 switches also perform a $2: 1$ concentration function and distributed in a specific pattern across the line junctor switch frames within the network. No concentration occurs in the line junctor switch frames.

2.05 The basic balancing unit in the $4: 1$ network is also the concentrator. However, concentration occurs in both stages; hence blockage may occur in both the A- and B-links. The A-links are particularly load sensitive because of the quarter-switch arrangement as shown in the following illustration. Study of the figure demonstrates that a poor distribution by class of service over the quarter-switches could result in blockage. The blockage could occur even though
from an overall hundred call seconds (CCS) load standpoint the concentrator could be underloaded.

STAGE 0 IN 4:1 NETWORK

## CLASS OF SERVICE

2.06 A good spread by class of service is also important in maintaining good balance. Using load measurements alone could lead to poor class-ofservice mix which could result in irregular variations
in concentrator load. Best use of line equipment can be obtained by including good load distribution with class-of-service spread. This procedure should result in load variations being spread across all the concentrators in an office.

## LOADING DIVISIONS

2.07 Normally the line equipment in a No. 1/1A ESS switch will consist of one loading division. Separate loading divisions (parent and child) can be created when there has been a recent addition or when networks have been marked for removal from a control group.
2.08 Parent and child loading divisions are indexed separately. This eliminates any unnecessary LBI penalties. A child loading division created because of an addition can be indexed separately as follows:

- A period up to 6 service evaluation months
- Until the line equipment reaches 30 percent of capacity.

When the child loading division reaches the sixth service evaluation month, it must be folded into the parent loading division.
2.09 A child loading division may also be created when line equipment has been designated for removal from a control group. A removal child does not have a time constraint. However, deloading of the line equipment should be accomplished as quickly as possible.

## LINE LINK NETWORK MODIFICATIONS

2.10 If an existing line link network (LLN) configuration is unsatisfactory because of equipment utilization or service, the existing arrangement can be modified. The options available to modify a network configuration in a working office are a B-link concentration ratio change (BCRC) and/or the mixed concentration ratio (MCRC) feature. A BCRC changes the existing line to junctor ratio to any other standard line to junctor ratio. This change must be within the existing design, either regular or heavy, of line concentration (ie, $2: 1$ or $4: 1$ ). The MCRC allows for a mixture of regular and heavy concentrators within the same office.

## B-LINK CONCENTRATION RATIO CHANGE

2.11 The development of the BCRC allowed for better utilization of terminal or CCS capacity. The BCRC only changes the line-to-junctor ratio (LJR). The LJR may be changed in an upward or downward direction. If a change is upward to a higher ratio additional line switch circuits may be added to each existing LLN. A downward BCRC to a lower LJR requires the removal of one or more line switch circuits from the existing full LLNs. Each LJR has a unique wiring pattern associated with it and that pattern must be changed when the LJR is changed. Therefore the B-links will always be rewired regardless of the direction of the BCRC.
2.12 A BCRC must result in a LJR that is currently rated as standard. Table A contains the current rating of all LJRs. The exception to this rule is the change of any existing heavy ratio to the $4: 1 \mathrm{H}$ ratio. The $4: 1$ is not standard and this exception is only allowed when performed in conjunction with an MCRC. Therefore for 2:1 (heavy) concentrator offices, a BCRC can be made from any existing heavy ratio to the $2: 1,3: 1$, or $4: 1$ heavy LJR. For $4: 1$ (regular) concentrator offices, a BCRC can be made from any existing regular ratio to the $4: 1$ or 6:1 regular LJR.
2.13 Examples of upward and downward BCRCs are provided in Fig. 1 and 2. In Fig. 1 a 4:1R to

6:1R BCRC is performed. This allows line switch circuits (LSC) 4 and 5 to be added to each LLN. Because the BCRC is in an upward direction, the addition of the new LSCs need not immediately follow the BCRC but can be postponed indefinitely. Figure 2 illustrates a downward BCRC from $6: 1$ to $4: 1$ and the required removal of LSC 4 and 5 from the existing LLNs. In this example, the LSCs are retained and along with new junctor switch circuits (JSCs) create two new LLNs.

### 2.14 All BCRC modifications are divided into steps

 that sequentially change the linkage pattern until the B-link pattern agrees with the new LJR. Each wiring step is accompanied by a parameter update that modifies the B-link parameter information to reflect the current state of the wiring changes. During each step there is a reduction in network switching capacity because one or two junctor switch circuits are removed from service for the duration of that step. Therefore BCRCs must be scheduled for low traffic periods. As long as the wiring steps are completed during low traffic periods there should not be any degradation of service.2.15 The BCRC capability has introduced the possibility of fractional networks in a No. 1/1A ESS switch. If an upward BCRC has been performed, it is not necessary to fill out all the networks to the complement required by the new LJR. Only the equipment required to meet the demand for the engineering period need be added coincident with the BCRC. If more than one fractional network appears as a result of this operation, the following recommendation should be considered. Only one size fractional network should exist in an office and all line switch circuits should be engineered at the same CCS capacity. Multiple loading divisions should not be considered.

## MIXED CONCENTRATOR RATIO FEATURE

2.16 The MCRC feature allows an office to operate with a mixture of heavy and regular concentrators. That is, this feature allows an office that is currently working with a heavy (2:1) concentrator LJR to grow with less expensive regular traffic (4:1) concentrators. Economic aspects must also be weighed when considering inclusion of the MCRC feature with an equipment addition.
2.17 Unlike the BCRC, the MCRC feature in itself does not require any modifications to the ex-
isting LLN equipment. When adding to an office a LLN that has a different type (ie, regular versus heavy) line switch or a different B-link ratio than the existing LLNs, then the MCRC will be used automatically.
2.18 If an MCRC is implemented in an office, the original LLNs should be administered utilizing one of the two options that follow:
(a) Leave the existing heavy LLNs as they are and treat them as fractional, 4:1R LLNs. For example, if the heavy LLNs were of the $3: 1 \mathrm{H}$ type, these would become $3 / 4$ equipped 4:1R LLNs (from a CCS capacity standpoint) coincident with the MCRC. If the heavy LLNs were of the $2: 1 \mathrm{H}$ type, these would be treated as though they were $1 / 2$ equipped 4:1R LLNs coincident with the MCRC. It should be noted that, under these arrangements, all fractional networks added on subsequent growth jobs must be the same size fractional as the heavy concentrator networks, since more than one size fractional network in an office is not recommended. In any case, the CCS capacity per terminal of the remaining heavy networks must be the same as the CCS/terminal capacity of a $4: 1 \mathrm{R}$ LLN coincident with MCRC implementation. Referring to Table A it can be seen that the CCS capacity per terminal of a $4: 1 \mathrm{R}$ LLN is $3: 59$ CCS. All existing heavy concentrator networks, regardless of size, now must be engineered to this capacity.
(b) In some cases, it can be economically feasible to BCRC the existing heavy LLNs to the $4: 1 \mathrm{H}$ LJR (if they are not at that ratio already). This arrangement has the advantage of building out the heavy networks to their "full" size (4:1H and $4: 1 \mathrm{R}$ networks have identical terminal capacities), thus allowing for any standard size fractional network on subsequent growth jobs. As mentioned in (a), a single loading division must be maintained for the LLN. Therefore, the CCS/terminal capacity of the 4:1H LLNs is equal to the CCS/terminal capacity of the 4:1R (3:59 CCS per Table A) LLNs.

## FEATURE RESTRICTIONS

2.19 There are two restrictions that affect the location of office equipment assignments.
2.20 Lines classified as essential are assigned to levels reserved for class A line load control. The number of levels needed will vary with office
parameters and is fixed in the parameter area of the program store. The following provides an illustration of the switches and levels required for each percentage of class A equipment.

| 2:1 TYPE CONCENTRATOR |  |  |
| :---: | :---: | :---: |
| \%LLC EQUIP'D | SW. No | LEVEL |
| 6.25 | 1,5 | 00 |
| 12.50 | 1,2,5,6 | 00 |
| 18.75 | 1,2,5,6 | 00 |
|  | 3.7 | 03 |
| 25.00 | 0,1,2,4,5,6 | 00 |
|  | 3,7 | 03 |
| 4:1 TYPE CONCENTRATOR |  |  |
| \%LLC EQUIP'D | sw. No | LEVEL |
|  |  |  |
| 6.25 | 0,1,2,3 | 04 |
| 12.50 | 0,1,2,3 | 04,08 |
| 18.75 | 0,1,2,3 | 04,08,15 |
| 25.00 | 0,1,2,3 | 04,08,15,00 |

2.21 Ground start is required for certain operations such as coin lines (except dial tone first) and some types of PBX direct dial trunks. Only even numbered equipment levels should be used for ground start lines. Levels should be preselected and wired for ground start service. Assignments should then be made accordingly. Additonal levels may be wired if demand for ground start service increases.

## DISTRIBUTING FRAME CONSIDERATIONS

2.22 The main distributing frame (MDF) provides a means of flexible assignment of cable pairs to line equipment. Although MDF considerations are not directly related to load balance, a poor distribution of line equipment or cable can limit access to certain portions of line equipment by causing frame congestion. Similarly, a poor or random assignment policy can create frame congestion by increasing jumper length.
2.23 To eliminate or limit frame congestion problems as mentioned in the preceding para-
graph, the initial layout and subsequent addition of cable and line equipment should be planned to provide optimum use of short jumpers without sacrificing load balance. The degree of planning required will vary with the type of MDF as well as the nature and size of the community being served. Large urban areas with high service order activity and serving several switching entities within a central office will require extreme care with MDF design.
2.24 A well engineered layout of cable pairs and line equipment along with reasonable preferential assignment procedures should result in optimum short jumper assigments. Establishment and maintenance of interdepartmental coordination is required to maintain long-range short jumper goals and continued good load balance.
2.25 If the criteria previously stated is adhered to, long jumpers should be kept to a minimum. Long jumpers will still occur because of cable transfer activity. These jumpers may be eliminated by the issuance of line equipment transfers (LETs). These may be scheduled to complete either before or after completion of the cable transfer. To and from ( T and F) service orders within the same wire center, where dual service is not required, should be assigned a new equipment that will result in a short jumper.
2.26 The following paragraphs provide general information about the several types of main frames currently available.
2.27 Conventional Frame: The conventional MDF contains two major components. A vertical side that is used to terminate outside plant cable pairs and a horizontal side, consisting of shelves, terminates line equipment and directory numbers (where appropriate).
2.28 Conventional MDFs can be constructed in lengths up to several hundred verticals. Therefore, they are especially susceptible to long jumper problems. To control jumper length, large MDFs should be segregated into assignment zones. The zones are the preferred areas of assignment for specified outside plant cables and central office line equipment. Local establishment of zones is necessary because of the variations in design and layout of conventional MDFs.
2.29 Establishment of zones should be an interdepartmental effort. The number of zones estab-
lished should be the minimum required to control jumper buildup on the horizontal shelves. Further information appears in Section 680-830-010.
2.30 Successful MDF zoning requires that line equipments be made available in all zones as required to meet inward movement. If a conflict should exist between machine loading and short jumpers, service objectives will take precedence over MDF considerations.
2.31 Modular Main Frame: Modular main distributing frames are designed for use in ESS offices. The frames are configured to be used with preferential assignment procedures which attempt to find the shortest cross-connections. The frame should only be used where approximately 95 percent of the jumpers can be expected to be made between adjacent verticals. Detailed descriptions of the frame can be found in Section 201-221-101.
2.32 The distributing frame module consists of ten verticals. Each pair of verticals is separated by a vertical jumper wire trough. The design is such that each outside plant vertical is adjacent to a line equipment vertical. Each file is considered to be divided into left and right half. A short jumper is defined as one that runs between terminals in adjacent half-verticals and thus lies wholly within a vertical trough. All other jumpers are defined as long jumpers. There are first- and second-choice long jumpers. The first choice is between terminals that may be separated by as many as ten verticals. The second choice is to run jumpers between terminals that are separated by ten or more verticals. Horizontal wiring troughs for running long jumpers are provided at the top and bottom of each frame. This trough space is limited, however, which makes it necessary to minimize long jumper assignments.
2.33 Although the design of the MDF is described as flexible, it requires many administrative controls to achieve its goal. The network administrator has two main concerns: to assign equipment preferentially by vertical and to maintain good load balance using the concept of spreading by class of service. These tasks are not small ones. The assignment lists should be prepared by MDF half-vertical and, when required, also by different classes of service.
2.34 Administering the assignment of equipment requires constant analysis of the load balance
results and careful surveillance of the records for long jumpers. Outstanding advance line equipment lists should be recalled by the administrator in order to withdraw line equipment that no longer meets specific load balance requirements.

### 2.35 Common Systems Main Interconnection Main Distributing Frame: The common

 systems main interconnection (COSMIC*) frame is a main distributing frame which terminates exchange cables and tie cables. It is associated with No. 1 ESS, No. 1 and No. 5 Crossbar, and Step-by-Step switching equipment.2.36 The COSMIC frame lineup consists of alternating modules of line equipment and exchange feeder cable pairs. Each module has 11 shelves which provide each feeder cable pair access, with a short jumper, to line equipment modules located immediately to the left and right.
2.37 Each module has an upper and lower express trough for routing long jumpers and a large vertical trough between modules for routing short jumpers. A COSMIC frame short jumper is defined as that jumper which does not route via the upper or lower express troughs when making connections of line equipments with an exchange feeder cable pair.
2.38 Incorporated with the COSMIC frame system is a mechanized Program for Arrangement of Cables and Equipment (PACE) which provides an efficient and consistent layout of exchange feeder cable pairs, line equipment, and tie cable pairs.
2.39 The COSMIC frame design depends on preferential assignments which combine load balance and class-of-service requirements with short jumper concepts. The Computer System for Main Frame Operations (COSMOS) is the mechanized system designed to aid in achieving these goals.

## 3. LOAD BALANCE INDEX

3.01 This part provides the administrator with an insight into the manual calculations required to develop a load balance index (LBI). More detailed information regarding the mechanized Load Balance System (LBS) is also included in Part 4 of this section. Information of a general nature including sta-

[^1]tistical and philosophical background are included in Section $780-350-050$. Normally No. 1/1A ESS switches will consist of one loading division. A recent addition of networks may result in parent and child loading divisions. These separate loading divisions should not exist for longer than 6 months. Removal child loading divisions do not have a time constraint. Further details are provided later in this part.

## MANUAL PROCEDURES

3.02 The following paragraphs provide an example of manual development of a LBI.
3.03 The first step in manual LBI development is to determine the engineered capacity (load) of each concentrator. The following illustration provides the engineered load (CCS/concentrator) for each concentration level.

| LINE <br> JUNCTOR <br> RATIO | LSF/C <br> PER <br> LN | CCS <br> PER <br> LSF/C | CONC. <br> PER <br> LSF/C | CCS <br> PER <br> CONC.* |
| :---: | :---: | :---: | :---: | :---: |
| Heavy | (Full) |  |  |  |
| $2: 1$ | 4 | 3,800 | 16 | 238 |
| $2.5: 1$ | 5 | 3,120 | 16 | 195 |
| $3: 1$ | 6 | 2,660 | 16 | 166 |
| $3.5: 1$ | 7 | 2,340 | 16 | 146 |
| $4: 1$ | 8 | 2,100 | 16 | 131 |
| Regular |  |  |  |  |
| $4: 1$ | 4 | 3,680 | 16 | 230 |
| $5: 1$ | 5 | 3,020 | 16 | 189 |
| $6: 1$ | 6 | 2,580 | 16 | 161 |
| $7: 1$ | 7 | 2,260 | 16 | 141 |
| $8: 1$ | 8 | 2,040 | 16 | 127 |

*Engineered Load
3.04 The next step is to determine the average load carried by each concentrator. For this example assume that an office is equipped with 4 (4:1R) LLNs, 4 line switch circuit (LSC)/LLN, 16 concentra-
tors/LSC. Also assume that 10 hours of data $=$ 391,390 CCS A-link usage. Then:

| Average |  | A-Link Usage |  |  |
| :---: | :---: | :---: | :---: | :---: |
| Hourly Load |  | No. Hrs. |  | Data |
| Average |  | 391,390 |  | 39,139 |
| Hourly Load |  | 10 |  | $\mathrm{CCS} / \mathrm{Hr}$ |
| Average | = | 39139 | = | 9785 |
| Load/LLN |  | 4 |  | CCS/LLN |
| Average | = | $\underline{9785}$ | = | 2446 |
| Load/LSC |  | 4 |  | CCS/LSC |
| Average | $=$ | 2446 | = |  |
| Load/Conc. |  | 16 |  | CCS/Conc |

3.05 To obtain the percentage of capacity of an office, divide the average load (AL) by the engineered load (EL) as follows:

$$
\frac{A L}{E L}=\frac{153}{230}=\begin{aligned}
& 66.5 \% \text { Capacity } \\
& \text { (Round to } 67 \% \text { ) }
\end{aligned}
$$

3.06 The next step is to determine the average holding time (AHT) of the calls creating usage on line equipments to obtain the AHT use one of the two following formulas:

$$
\begin{aligned}
& 2 \text { (L to L Junctor Usage) } \\
& + \text { (L to T Junctor Usage) } \\
& \hline \text { Originating PC } \\
& + \text { Total of LLN PC } \\
& + \text { IAO PC } \\
& \quad \begin{array}{l}
\text { A-Link Usage } \times 1.05 \\
\hline \text { Originating PC + Incoming PC }+ \text { IAO PC }
\end{array}
\end{aligned}
$$

3.07 The AHT should be calculated for each day and then an average for the week should be obtained. If data is lost and the average is less than 5 days, be certain that the data results in a good or reasonable holding time. If the data is questionable, then a recent previously computed AHT should be used.
3.08 The two items obtained in paragraphs 3.05 and 3.06 are used to obtain the quality control limit (QCL). The QCL is determined by using Table $B$ and the following steps.
(a) Assume that the AHT developed from the formula in paragraph 3.06 is equal to 174 seconds.
(b) Under the AHT column in Table B, find 174 seconds. Note that it falls between 171 and 190 seconds.
(c) Find the percentage of capacity in Table B. To locate 67 percent (paragraphs $3.03,3.04$, and 3.05), turn to sheet 2 of the table (ie, 67 percent falls between 66 and 75 percent)
(d) Next locate the correct LJR under the previously identified capacity column (230, 4:1R).
(e) The QCL is read out from the juncture of the AHT line and the LJR column. For this example the $\mathrm{QCL}=22$.
3.09 Details of the use of the QCL in establishing the parameters of a normal distribution curve are provided in Section 780-350-050.

## SCORE DEVELOPMENT

3.10 Use of a normal distribution curve and the related usage values can become awkward when dealing with large numbers and many concentrators. A scoring system has been developed to simplify the process. The scoring system takes the large usage values from the normalized curve and represents them with simple numbers. Each number is assigned to represent the distance each concentrator is from the average concentrator.
3.11 The numbers used in the scoring system are defined as follows:
(a) Each concentrator with exactly average CCS is assigned a score of zero.
(b) Each concentrator, either above or below average, up to and including 1.5 standard deviations (ie, one half the QCL) is assigned a score of either +1 or -1 .
(c) Each concentrator, either above or below the 1.5 standard deviation previously defined but not exceeding 3.0 standard deviations is given a score of either +2 or -2 .
(d) Each concentrator, either above or below 3.0 standard deviations from the average is assigned a score of +4 or -4 . A 4 is used to point up those concentrators that are severely underloaded or overloaded.

## PENALTY POINTS

3.12 The LBI is developed using a 3 -month rolling average. The most recent results are weighted most heavily. This is done by assigning penalty points as follows:
(a) Concentrators are assigned three penalty points for a +4 on the current month's study.
(b) Two penalty points are applied to a +4 score on the preceding study
(c) One penalty point is given for $a+4$ score on the next preceding study.

Each concentrator can collect a maximum of six penalty points. The following provides an example of the use of penalty points.

|  | NOV. | DEC. | JAN. | TOTAL |
| :---: | :---: | :---: | :---: | :---: |
| Conc. A |  |  |  |  |
| Study Score | +4 | +4 | +4 | - |
| Penalty Points | 1 | 2 | 3 | 6 |
| Conc. B |  |  |  |  |
| Study Score | +4 | +1 | +4 | - |
| Penalty Points | 1 | 0 | 3 | 4 |
| Conc. C |  |  |  |  |
| Study Score | -1 | +4 | +2 | - |
| Penalty Points | 0 | 2 | 0 | 2 |
| Conc. D |  |  |  |  |
| Study Score | +4 | +1 | -1 | - |
| Penalty Points | 1 | 0 | 0 | 1 |
| Conc. E |  |  |  |  |
| Study Score | -2 | +1 | +4 | - |
| Penalty Points | 0 | 0 | 3 | 3 |
| Conc. F |  |  |  |  |
| Study Score | +1 | -1 | +1 | - |
| Penalty Points | 0 | 0 | 0 | 0 |
| Conc. G |  |  |  |  |
| Study Score | +4 | +2 | +2 | - |
| Penalty Points | 1 | 0 | 0 | 1 |

## PENALTY POINT FRACTION

3.13 The penalty points are totaled for a loading division and a penalty point fraction (PPF) is calculated. The PPF is determined by dividing the number of penalty points by the number of valid concentrators in the loading division as follows:

$$
\begin{array}{ll}
\text { Valid Concentrators } & =200 \\
\text { Penalty Points } & =60 \\
\text { Penalty Point Fraction } & =\frac{60}{200}=0.3
\end{array}
$$

## WEIGHTED PERCENTAGE OF CAPACITY

3.14 The percentage of capacity that an office is working at is used for the LBI. A factor is used to emphasize the most current data. The weighted capacity is obtained in a manner similar to penalty points. The following illustrates a weighted capacity.

|  | DEC. | JAN. | FEB. | TOTAL |
| :--- | :---: | :---: | :---: | :---: |
| Percentage of <br> Capacity <br> (Loading Division) | 65 | 66 | 71 | - |
| Weight | 1 | 2 | 3 | 6 |
| Total <br> Weighted <br> Percentage of <br> Capacity | 65 | 132 | 213 | 410 |

## RAW LOAD BALANCE INDEX

3.15 A raw LBI is obtained by entering Table C with the PPF and the weighted percentage of capacity (paragraphs 3.13 and 3.14 ). The raw LBI is found at the intersection of these two values. For example, an office at 68 percent capacity with a PPF of 1.46 has a raw LBI of 99 .

## HOT SPOTS

3.16 The raw LBI measures the state of balance of a given office. However, the raw LBI does not consider excessive overload conditions. Concentra-
tors with excessive usage are provided for by the introduction of hot spots. The hot spot concept establishes a threshold that equals a high probability of blocking. A concentrator with usage above the threshold is considered a hot spot. Hot spot penalty points are then assigned based on the performance of the concentrator.
3.17 Table D provides threshold values for all No. 1/1A ESS switch LJRs. The concentrator usage measurments for the current and two previous studies are compared to the proper threshold value. Hot spot penalty points are applied to the concentrators as follows:
(a) Concentrators are given three hot spot penalty points for a hot spot in the current month's study.
(b) Two penalty points are assigned for a hot spot on the preceding study.
(c) One penalty point is applied for a hot spot on the next preceding study.
(d) Furthermore, if a hot spot occurs for two consecutive studies, an additional penalty point is applied.
(e) If hot spot penalty points exist for all three studies, two additional penalty points are applied.
(f) Therefore, a concentrator can collect a maximum of eight hot spot penalty points.
3.18 Hot spot penalty points are accumulated for an entire loading division and a hot spot penalty point fraction is calculated. The hot spot PPF is obtained by dividing the number of hot spot penalty points by the number of measured concentrators in the loading division. An example of a hot spot PPF follows:

$$
\begin{aligned}
\text { Measured Concentrators } & =300 \\
\text { Hot Spot Penalty Points } & =25 \\
\text { Hot Spot PPF } & =\frac{25}{300}=0.08
\end{aligned}
$$

3.19 The hot spot PPF is read into Table E and a hot spot correction is obtained. Using the ex-
ample, a hot spot PPF of 0.08 converts to a hot spot correction of 3 .
3.20 The hot spot correction factor is then subtracted from the raw LBI. The result is the LBI. For example:

```
Raw LBI = 99
Hot Spot Correction = - = 3
LBI =
```

3.21 If a No. 1/1A ESS switch has parent, and child loading divisions or has received an MCRC, the LBI calculations are somewhat different than the examples in the preceding prargraphs. The following paragraphs provide information on the different calculations.

## MCRC OFFICES

3.22 Offices with MCRC are handled as one loading division. The engineered capacity for the heavy (2:1) ratio concentrators is taken to be one-half that of the regular (4:1) concentrators. The formula for establishing the office capacity follows:

```
Loading Div. EL* (No. 4:1 Conc.)
Capacity
    + EL*
*EL = The engineered load CCS/concentrator
    from the illustration in paragraph 3.03
```

For example, if $4: 1$ concentrators are added to an existing $2: 1$ office, the capacity will be:

$$
\begin{array}{ll}
\text { Loading Div. } & =230 \mathrm{CCS} \times 96+\frac{230 \mathrm{CCS}}{2} \times 384 \\
\text { Capacity } & =22080+44160=66240 \mathrm{CCS}
\end{array}
$$

3.23 The percentage of capacity and the average holding times for MCRC offices are found in the same way as described previously (paragraphs 3.03 through 3.06).

## QCL

3.24 The QCL for the $4: 1$ concentrators in an MCRC office is read directly from Table B. The QCL for the heavy (2:1) portion of the office is obtained by
multiplying the $4: 1$ QCL by 1.414 . For example, if the 4:1 QCL in an office is equal to 22 , then the 2:1 QCL will equal $22 \times 1.414$ or 31 .

## SCORES

3.25 The scores for the 4:1 and 2:1 concentrators are developed as described in paragraphs 3.10 and 3.11. However, the scores for each group of concentrators (each ratio) is developed separately using the respective QCLs.

## PENALTY POINTS

3.26 Penalty points are determined in the same manner as previously described. However, the penalty points for each ratio will be added separately.

## PENALTY POINT FRACTION

3.27 The PPF is calculated by using the following formula:

$$
\text { PPF }=\frac{\begin{array}{l}
\text { No. of } 4: 1 \text { Penalty Pts. } \\
+1 / 2 \text { No. of } 2: 1 \text { Penalty Pts. }
\end{array}}{\begin{array}{l}
\text { No. of } 4: 1 \text { Conc. } \\
+1 / 2 \text { No. of } 2: 1 \text { Conc. }
\end{array}}
$$

## RAW LBI

3.28 The raw LBI for MCRC offices is obtained by entering Table $C$ with the weighted percentage of capacity and the weighted PPF obtained in the preceding paragraph.

## HOT SPOTS

3.29 Obtain the threshold value for each ratio in the office from Table D. Apply the hot spot penalty points in the same way as single ratio offices.
3.30 Count the number of hot spot penalty points assigned to regular concentrators and to heavy concentrators. The hot spot PPF is obtained by weighting the points assigned to the concentrators. The MCRC hot spot PPF is found as follows:
Hot

| Spot |
| :--- |
| PPI |$=\quad$| No. of Reg. Hot Spot Penalty Pts. |
| :--- |
| $+1 / 2$ No. of Heavy Hot Spot Penalty Pts. |

| No. of Reg. Conc. |
| :--- |
|  |
| $+1 / 2$ No. of Heavy Conc. |

3.31 Read the hot spot PPF into Table E and obtain the hot spot correction factor. Subtract the hot spot correction factor from the raw LBI. The result is the LBI.

## PARENT AND CHILD LOADING DIVISIONS

3.32 Separate parent and child loading divisions are allowed to exist when there has been a recent addition or when networks are to be removed from a control group. When separately indexed parent and child loading divisions with different concentrator ratios exist, the calculations will be performed as though the networks were combined in a single MCRC loading division.

## 4. LOAD BALANCE SYSTEM

4.01 The Load Balance System (LBS) is a portion of the Total Network Data System (TNDS). The LBS provides mechanized computation of the LBI as well as assignment and balance guides for offices that do not use a mechanized line assignment system.
4.02 The following paragraphs provide a brief description of the input documents needed to enter a No. 1/1A ESS switch into LBS. Any related Bell Information System Practice (BISP) is also provided.
4.03 In order to use LBS, the No. 1/1A ESS switch must be established in the Common Update (CU) system of TNDS. This process is covered in BISP 756-370-253.

TRAFFIC UNIT RECORD-600 DOCUMENT (756-370-351 BISP)
4.04 This document informs the LBS that the new ESS office exists and is planning to process load balance data through TNDS. The 600 is the base record, and must be input and accepted by CU before any of the other 6XX-series forms can be processed. The 600 document tells LBS the following:

- Who is responsible for the new ESS switch, through area level
- Exactly which office it is by the 11-character Common Language Location Identification (CLLI) code from the TU100, a CU output
- The first scheduled load balance study start date
- Whether LBS will be used to process all the load balance data, or just to report "manually" derived load balance indices.

TRAFFIC UNIT CHARACTERISTICS-601 DOCUMENT (756-370-351 BISP)
4.05 The 601 document is an extension of the 600 . It further describes the office which was described in the 600 document. The key information on the input is as follows:

- Total unit (total office) main stations, which must be updated, in some manner, monthly.
- Additional information needed to process manual load balance data, if applicable,
- Reason(s) for not reporting an LBI for a given month.

LOADING DIVISION IDENTIFICATION-620 DOCUMENT (756-370-353 BISP)
4.06 The 620 document identifies each loading division in the office, even if (as is the case with most ESSs) there is only one. For each loading division, the 620 document specifies whether the equipment being studied is as follows:

- Indexed (as are all loading divisions over 30 percent CCS capacity).
- Nonindexed (such as the trunk link grids, currently).
- Child/Fractional: Child meaning either new equipment which has just been added to the office and has 6 months to become loaded to the same level as the old established concentrators or old equipment which is about to be removed. The child loading division is described further in the 625 document.
- Fractional: Refers to fractional LLN, whose concentrators do not have the same junctor ratio.
LOADING DIVISION CHARACTERISTICS-621 DOCUMENT (756-370-353 BISP)
4.07 The 621 document is an extension of the 620 document, further describing the parent (not
child) loading division(s) which were defined in the 620 . Its most important inputs are, per loading division,
(a) The division's engineered CCS capacity
(b) The average holding time (AHT) of the average main station during the load balance busy hour. This value must also be updated with each load balance study
(c) The average CCS/main station, and whether that CCS is "average" or "light." This will affect the balance guides generated by LBS.
(d) Assignment guide print options are as follows:
(1) Whether to print a line assignement guide, and, if so, how long to make it.
(2) Whether or not to print a LET, and, if so, how long to make it.
(3) Whether or not a line assignment guide (LAG) for just the parent (no child) line equipment is desired.
(4) Whether the data summary (DS) generated should include all concentrators in each loading division, or just the exceptions those failing checks. When current load balance results are unacceptable or questionable, the long $\boldsymbol{D S}$ should be requested.

SPECIAL OFFICE CHARACTERISTICS-605 DOCUMENT (756-370-351 BISP)
4.08 The 605 document differentiates between LLNs which have $2: 1$ concentrators, and those which have $4: 1$ concentrators, in those offices (1AE5 or later) which have both. This must be input to index an MCRC unit.

## ASSIGNMENT DIVISION RECORD-610 DOCUMENT (756-370-352 BISP)

4.09 The 610 document is used when two or more separate loading divisions are deemed similar enough to be loaded comparably. This document would apply to an office with MCRC. However, it could apply to loading divisions, originally segregated by main distributing frame zoning which are now to be combined and accessed equally for line assigning, regardless of cable pair location.

CHILD LOADING DIVISION RECORD INPUT-625 DOCUMENT (756-370-354 BISP)
4.10 This document defines temporary "child" loading division(s) with "parent" loading divisions which are indexed.

- Any loading division whose current CCS load is under 30 percent of its engineered capacity is not indexed.
4.11 The 625 document denotes whether the child loading division is growth or removal equipment. Child loading divisions are most likely to be growth unless the office is about to undergo an area transfer or a B-link concentration change (BCRC) to decrease its line-to-junctor ratio, and increase the number of B-links per line switch frame/circuit by having existing line switch frame circuits removed.
(a) The TNDS-LBS will automatically include a growth child loading division in the parent loading division after 6 months have passed. In the meantime, the child should be loaded to look as much like the parent loading division as possible. This will minimize the discrepancy in load balance after the two are joined for reporting and assigaing purposes.
(b) A removal child may continue on as a separate division indefinitely. It does not have its equipment included on any of its parent's balance guide reports. A removal child may have its own balance guide reports generated, if necessary.

HISTORY CHANGE INPUT-690 DOCUMENT (756-370355 BISP)
4.12 The 690 document allows selected editing of previously processed load balance data. A past LBI may be recomputed only if the average holding time and/or CCS capacity for any loading division were out-of-date when that index was first computed. Invalid W schedule data must be deleted from the LBS history files before generating official company load balance results for the service observing month.

## MANUAL TRAFFIC REPORTING INPUT-691 DOCUMENT (756-370-355 BISP)

4.13 Those ESS switches which are not fully on LBS may input their manually derived LBI on this document, so that all end office indices may be consolidated at the district level.

## LBS OUTPUT REPORTS

4.14 A listing of the available LBS output reports is provided as Table F. Detailed information on the content of these reports is contained in BISPs 756-370-321 and 756-370-324.
4.15 Examples of some typical LBS reports are included as Fig. 3 through 8. The reports provided are:
(a) TL720 Traffic Unit Index-Addendum: It is an interim LBI that is produced every week that
LBS data is processed.
(b) TL732 Data Summary: This report provides the 3 -month load balance history for each concentrator in the office. This report also provides summarized statistics of the latest load balance study and the overall office status.

## 5. TRUNK LINK NETWORK BALANCE

5.01 The NSA is responsible for scheduling and surveillance of trunk link network (TLN) and trunking data. This data is then provided to personnel in other centers (eg, Circuit Provisioning Center [CPC]) for action. The following paragraphs provide a description of the various trunk link network configurations. A brief description of NSA functions is also provided.
5.02 Full TLNs consist of four trunk junctor switch circuits and a full complement of trunk switch circuits (TSCs). The number of TSCs is dependent on the trunk-to-junctor ratio (TJR). A listing of valid TJRs is provided in Table G.
5.03 It is possible to have a fractional TLN in an office. Only one fractional size TLN is permitted in an office but any number of TLNs in an office can be fractional. Fractional size is determined by the ratio of TSCs installed to the full complement of TSCs for a given concentration ratio. For example, four TSCs out of a possible six TSCs, with a 1.50:1 TJR, equals a $2 / 3$ fractional TLN.
5.04 The load unit in a TLN is the trunk grid which is basically equivalent to a concentrator in a LLN. The switching stages in the TLN are the same as in a LLN.
5.05 The TLN balance and trunk grid balance within the networks can have an impact on
customer service. Incoming matching loss and loss of TLN capacity may both be a result of poor grid balance. To ensure good balance results, the NSA should provide surveillance, data, and coordination.
5.06 The NSA provides basic trunking data by scheduling trunk grid data from the W schedule. The data is processed downstream via TNDS in a manner similar to that used for LLNs. The grid usage printouts are sent to the CPC for review and action if necessary.
5.07 Although the grid usage printouts are sent to the CPC, the NSA should be familiar with the content and meaning of these reports. For No. 1/1A ESS switches, the reports can be sorted numerically or by CCS correction valves (see Fig. 9 and 10). The information contained on the reports is defined as follows:

- \% of LD AVG - the percentage that a grids load is of the loading divisions average load
- PROJ CCS-the amount of usage based on the current usage and the usage history of the grid
- RAW CCS CORRECTION--the amount of CCS correction required (plus or minus) to bring a given grid close to the average load of the grids in the loading division
- HIST WEEKS-the number of study weeks in the history file for a particular grid.
5.08 Since the correction figures shown are "raw," some caution should be used when attempts are made to balance the load between grids. The NSA should also use the available NORGEN reports when performing trunk analysis. If imbalance problems do occur, the NSA will notify the CPC, then coordinate any required trunk rearrangement(s) with the SCC and the CPC.

Note 1: All ferreed LJR s are rated A\&M or MD since ferreed LLN equipment is rated A\&M
Note 2: CCS capacity of fractional network = size of fractional network X CCS capacity per full LLN
Note 3: CCS per line terminal reflects the CCS per installed line termination. It can be used as follows
(a) CCS per line terminal $\div$ actual line fill = maximum CCS per working line.
b) CCS per tine terminal $\div$ CCS per working line $=$ maximum line fill

TABLE A (Contd)
LIN CONFIGURATION AND CAPACITIES

| 6:1 R | A \& M | $\begin{aligned} & 1 / 6 \\ & 1 / 3 \\ & 1 / 2 \\ & 2 / 3 \\ & 5 / 6 \\ & \text { Full } \end{aligned}$ | $\begin{aligned} & 1 \\ & 2 \\ & 3 \\ & 4 \\ & 5 \\ & 6 \end{aligned}$ | 4 | $\begin{aligned} & 1024 \\ & 2048 \\ & 3072 \\ & 4096 \\ & 5120 \\ & 6144 \end{aligned}$ | 2580 | 15480 | 2.52 |
| 7:1 R | MD | $\begin{gathered} 1 / 7 \\ 2 / 7 \\ 3 / 7 \\ 4 / 7 \\ 5 / 7 \\ 6 / 7 \\ \text { Full } \end{gathered}$ | $\begin{aligned} & 1 \\ & 2 \\ & 3 \\ & 4 \\ & 5 \\ & 6 \\ & 7 \end{aligned}$ | 4 | $\begin{aligned} & 1024 \\ & 2048 \\ & 3072 \\ & 4096 \\ & 5120 \\ & 6144 \\ & 7168 \end{aligned}$ | 2260 | 15820 | 2.21 |
| 8:1R | MD | $\begin{aligned} & 1 / 8 \\ & 1 / 4 \\ & 3 / 8 \\ & 1 / 2 \\ & 5 / 8 \\ & 3 / 4 \\ & 7 / 8 \\ & \text { Full } \end{aligned}$ | $\begin{aligned} & 1 \\ & 2 \\ & 3 \\ & 4 \\ & 5 \\ & 6 \\ & 7 \\ & 8 \end{aligned}$ | 4 | $\begin{aligned} & 1024 \\ & 2048 \\ & 3072 \\ & 4096 \\ & 5120 \\ & 6144 \\ & 7168 \\ & 8192 \end{aligned}$ | 2040 | 16320 | 1.99 |

Note 1: All ferreed LJR s are rated A\&M or MD since ferreed LLN equipment is rated A\&M
Note 2: CCS capacity of fractional network = size of fractional network $\times$ CCS capacity per full LLN
Note 3: CCS per line terminal reflects the CCS per installed line termination. It can be used as follows:
(a) CCS per line terminal $\div$ actual line fill $=$ maximum CCS per working line.
(b) CCS per line terminal $\div$ CCS per working line $=$ maximum line fill.
