1. GENERAL

1.01 This section describes the contents of recent change (RC) message program listings, system acknowledgment, and RC18 and RC16 output messages. This information applies to the 2-Wire No. 1 Electronic Switching System (ESS) (through 1E5 generic programs). General RC information is given in Section 231-118-321.

1.02 This section is reissued for the following reason:

(a) To delete generics prior to 1E3.

(b) To add more detail to pident contents and layout description (Part 2).

(c) To make minor corrections as required.

Program Listing

1.03 A program listing (PR) consists of a computer generated hardcopy list of program instructions and related information for one or more program
units identified by program identifications (pidents).
A pident is that segment of a program that is compiled as a unit by a compiler program (on a general purpose computer). Most PRs consist of a single pident; only a few contain more than one. This listing produced as a result of this compilation becomes the PR or a part of it if pidents are combined to perform a system function. No pident is split between PRs. The PR contains an index sheet which lists the pidents it contains and their issues, followed by the listings for each pident. PRs are numbered as PR-IA... for No. 1 ESS (... is some unique 3-digit number).

Program Identification

1.04 The recent change message interpretation programs form a system to interpret RC input messages, check them for validity, and assemble the input data into the proper format for storage in translation memory. The RC message system consists of over 70 message pidents (1 per message), 10 code (or control) pidents, and 2 pidents shared by all the message pidents. The message pidents are tables of data defining the messages and the control pidents are the programs of executable code (ie, ESS instructions) that perform the functions of the RC message system. Many of these functions are accomplished by applying fixed algorithms to the data in the message tables; therefore, a substantial portion of the system is table driven by the message pidents.

1.05 Table A lists the 12 nonmessage pidents, a representative message pident, and references to associated PR documents. A brief description of the function of the control, shared, and message types of pidents shown in Table A follows.

* Two Letters Identifying a Message
+ 21, 22, ... nn

Control Pidents

- **RCIG** (Initialization and General Control)—Determine availability of the RC system for the first line of the message and directs the flow of control among other modules in the RC system.

- **RCIE** (Input Editor)—Links the input/output terminal (IOT) buffer and the RC message processing system.

- **RCKI** (Keyword Input)—Performs processing and local error checking of RC message keyword units.
• **RCVC** (Validity Checks)—Assures valid translation data base transitions.

• **RCTF** (New Pass Translation Format)—**RCCH** (Change Pass Translation Format) and **RCFI** (Format Interpretation)—The format section builds images of translation data in the RC work list and RC auxiliary area on NEW and CHG messages and retrieves translation data from program store and RC area on CHG and OUT messages.

• **RCWL** (Work List Processing)—Processes the work list (WL) entries made by the message pidents.

• **RCDY** (Delayed Order)—Processes delayed service order by storing message storage buffer (MSB) input in a delayed activation block (DAB) for future reloading in the MSB.

**Shared Pidents**

• **RCTS** (Table Subroutines)—Consists of special purpose subroutines used by work list pident RCWL and the RC message pidents.

• **RCST** (Shared Information)—Consists of five data tables which are shared by several of the code (control) pidents during RC message processing.

**Message Pidents**

• **RCxx** —In general there is a message pident for each type of translator. The message pident is made up of data tables which provide the decision information to control the processing flow of the associated code (control) pidents.

**System Acknowledgment**

1.06 The system’s response to an RC input message is a TTY acknowledgment (TACK). If at anytime during an RC message input an input control character (!, %, , &, or &) is received, the system responds immediately with some form of TACK. The TACK is immediate, in that, no other output message can intervene. The type of TACK received will indicate correct or incorrect input of message, or some system condition preventing acceptance of the input message. See Part 3 for a detailed description of the various TACK responses.

**Output Message (OM)**

1.07 The ESS provides RC18, RC16, and/or RC FAILURE output message in response to the RC input messages. Twenty-one types of RC18 messages are available to indicate accepted RC messages, irregular system conditions affecting RC messages, or rejected RC messages that contain errors (see Part 4). The RC16 output messages consist of data (in octal) for use as an aid in the analysis of an error resulting from the generic program. These OMs have a lower priority rating than a TACK and could be delayed by some higher priority message.

2. DESCRIPTION OF RECENT CHANGE MESSAGE
PROGRAM LISTINGS

2.01 A separate message pident is provided for each RC input message with the exception of the delayed mode activation message RC:ACT which is contained in control pident RCDY (RC delay order) PR-1A308. Table B displays the RC input messages and their corresponding pidents, PR numbers and message indexes. Each pident is provided with a message head table, an input section, a validity section, a translation format section, and an error dictionary section which is useful in the interpretation of RC18 and RC16 output messages.

**PROGRAM LISTING PAGE FORMAT**

2.02 The PR follows a standardized format in presenting significant information about the program. The pident name consists of four alphabetic characters PPPP; the pident issue consists of up to seven alphanumeric characters PPPPPAAA. The first four characters must be identical to the program name. The remaining three characters identify the generic program. At the top of each page is a title line giving the time and date of assembly, the pident name and generic program number, the issue number of the associated compool libraries, and the version number of the program. At the bottom of each page is a title line giving the pident name and program generic number, issue number, page number, and the PR number.

</table>
(Fig. 1). In addition, within the program section, every program unit will start on a new page and have the program unit name at the top of each page.

**PROGRAM LINE FORMAT**

**2.03** Each line in the program section of a PR contains a specified set of fields of information. It is not necessary for each line to include all fields of information as this depends on the type of instruction. The line format may include:

(a) Octal machine language
(b) Decimal numbers denoting line numbers
(c) Source data set line numbers
(d) Marco generation level numbers
(e) Program language statement
(f) In-line comments.

Figure 1 provides a layout of the line format and Table C gives a description of columns on the line format.

**A. Pident Introduction**

**2.04** Each pident starts with Generic Feature Information and a Program Administration Section. The Generic Feature Information includes the generic and PR number and provides in feature and package parameters that are set for the particular assembly. The Program Administration Section includes program corrections (if any) that are included in the assembly.

**B. Message Head Table**

**2.05** The message head table follows the Program Administration Section and contains the following:

- Pident message identification
- Relative address of associated tables
- Types of RC messages allowed (NEW, CHG, OUT)
- Number of associated keyword units
- Number of MSB (message storage buffer) entries

**Note:** The message storage buffer is a storage facility in the call store area. The MSB consists of the MSB proper and auxiliary areas. The MSB proper consists of a one-word entry assigned for each keyword in the RC message, and the MSB auxiliary area is for use when the one-word entry is inadequate to store the keyword data.

**C. Definition and Reference Tables**

**2.06** At the end of the pident program section, a list of symbol references and a list of macros are provided. Each symbol (name) appearing in the pident is listed and referenced to the page and line numbers of its occurrences. Figure 2(A) provides a layout of the definition and reference tables and Table D gives a description of the columns on the definition and reference tables.

**2.07** A separate list of macros are provided as part of the cross reference list (following the symbol references) providing the count or times a macro is used within a pident and the page and line reference numbers applicable to the macro call. Refer to Fig. 2(B) for an example. The columns of the cross reference list and their corresponding descriptions are listed in Table D.

**INPUT SECTION**

**2.08** The input section, following the message head table, always contains a keyword table. It may also contain an internal keyword table, a keyword equivalence table, and a keyword collision table. The input section is concerned with reading in data. A description of these four tables is given in paragraphs A through D.

**A. Keyword Table**

**2.09** The keyword table contains all valid keywords for the message in condensed bashed form. This hashed form is a number created by combining the keyword character codes according to an arbitrary but fixed algorithm to achieve a compact code for the total keyword.
<table>
<thead>
<tr>
<th>FIELD OF INFORMATION</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>RELATIVE ADDRESS</td>
<td>Octal representation of the displacement of the instruction or data that has been translated by SWAP on that line of the program listing. In each pident, the 6-digit address begins with 000000; the number identifies the relative location of the word.</td>
</tr>
<tr>
<td>ABSOLUTE ADDRESS</td>
<td>(Core loaded program). The actual program store or call store address of the instruction.</td>
</tr>
<tr>
<td>ENCODED PROGRAM INSTRUCTION</td>
<td>Octal representation of the encoded program instruction or data. In No. 1 ESS the 13 digits to the right of each relative address represents an instruction or data containing 37 binary bits. In No. 1A ESS there are 8 digits to the right of the relative address containing 24 binary bits. In No. 1 ESS the three preceding 12-bit words are used to derive this data statement. In No. 1A ESS only two 12-bit words are used. This column may also contain relative octal addresses of the EQU pseudo-operation. In the case of recent change PRs this column may contain the octal representation of a macro expansion.</td>
</tr>
<tr>
<td>ADDRESS VALUE</td>
<td>One alpha character that denotes that the address computation for the instruction may not be complete and tells what the loader will do to complete the address computation for the instruction. “R” denotes relative address meaning that the loader does nothing to the address. “L” denotes local (absolute) address meaning that the loader will add in the starting address of the pident to the address. “V” denotes “extern” or a reference to an address external to this program which is resolved by going through the transfer vector table. It tells the loader to find the symbols address in the transfer vector table. “X” denotes “direct” or a reference to an address external to this program which should be resolved without an entry in the transfer vector table.</td>
</tr>
<tr>
<td>SOURCE DATA SET LINE NUMBER</td>
<td>A decimal number which specifies a line in the source data set. The lines of the source data set are continuously numbered from the beginning to the end of the program listing and are used when modifying a source program. The format of the source data set line number may be XXXXX.XXXX or XXXXX., where X is a decimal digit.</td>
</tr>
<tr>
<td>MACRO GENERATION LEVEL NUMBER</td>
<td>A level number which identifies which level of nested macros generated this line of the program listing. (A nested macro is a macro that is called by another macro.) The macro level number format is “-XXX-” where X is a decimal digit. Those lines which include macro level numbers are macro or EPL expansions produced by the assembler program from the last source data set line preceding the macro expansion line.</td>
</tr>
<tr>
<td>PAGE LINE NUMBER</td>
<td>Decimal digits denoting a line (01 to 50) per a page of a program listing.</td>
</tr>
<tr>
<td>LOCATION FIELD</td>
<td>A symbolic name (address) of a program point by which other instructions may refer to the instruction named. Such symbolic names are required at points to which control is transferred.</td>
</tr>
<tr>
<td>OPERATION FIELD</td>
<td>Symbolic instruction operation code, macro name, or pseudo-operation instruction code. The instruction code can consist of one to seven letters; macro names can be larger.</td>
</tr>
<tr>
<td>VARIABLE FIELD or OPERAND FIELD</td>
<td>Contains the parameters related to the operation designated in the operation field. The variable or operand field is formed by several subfields.</td>
</tr>
<tr>
<td>COMMENTS FIELD</td>
<td>Begins with a number sign (#) and contains comments, remarks, or references made by the programmer to aid in the maintainability and usability of the program listing.</td>
</tr>
</tbody>

PR-1A336

RCLI015  ISSUE 4  PAGE 135

Page 9/10
2.10 For each keyword, the table contains the following:

- Hashed form of the keyword.
- Either a description of the data that must accompany the keyword (including limited number of basic checks, such as type of data, number of digits, etc) or an index into the supplementary data assembly Table for more complex forms of keyword data.
- An indicator for allowing the keyword to be repeated in segmented messages.

B. Internal Keyword Table

2.11 The internal keyword table is actually part of the keyword table and is located at the end of the keyword table. The internal keyword table contains no user inputted keywords. It is merely a list of keywords used internally by the message pident. The purpose of this table is to assign MSB locations and truth value indexes to the internal keywords.

C. Keyword Equivalence Table

2.12 The keyword equivalence table will be located immediately after the internal keyword table. Entries in this table are made in order to specify any alternate names for keywords listed in the keyword table. The table contains:

- Hash code of alternate name
- Keyword index of the equivalent keyword in the keyword table.

D. Keyword Collision Table

2.13 The keyword collision table is located immediately after the keyword equivalence table. Entries are made into this table when two keywords have the same hash code. Each entry contains:

- Complete character codes for the collision keyword.
- Keyword index of the keyword in the keyword table.

VALIDITY SECTION

2.14 The validity section of a message pident always contains a data check table, validity (tree) table and a format selector table for each message type (NEW, CHG, OUT or equivalents) allowed by the message. In some cases, the validity tables for CHG messages will be combined with the validity tables for OUT messages. The validity section is concerned with whether the input data is valid. Following is a description of the three basic types of validity tables.

A. Data Check Table

2.15 The data check table contains the following:

- The detailed checks performed on keyword data which includes comparing keyword data with translation values, checking translations assignments, and testing for specific values of keyword data.
- The algorithms to calculate internal keyword value.

B. Validity (Tree) Table

2.16 The validity (tree) table specifies and contains the following:

- The valid combinations of keywords and keyword data by establishing a validity tree (each node on the tree is provided a name).
- A keyword (KW) value for each node and a set of tests that must be passed to set the truth value bit for a particular node. Some nodes cause RC18 messages to be printed if they fail the set of tests. In such cases, reference to the proper (NEW, CHG, or OUT) validity (tree) error dictionary (paragraph 2.29) will be required to determine the error.

C. Format Selector Table

2.17 The format selector table contains a set of Boolean operations to be performed upon the truth value bits to derive the format selector bits which control the execution of the translation format table.
TRANSLATION FORMAT SECTION

2.18 The translation format section always has a translation format table and may have a change transition screening table, change keyword list, and a change YES/NO keyword list. This section is concerned with the format of the translation output of the message. A description of the tables contained in this section is given in subparagrapgh A through D.

A. Translation Format Table

2.19 The translation format table contains the data format description of the translator words changed by the RC message. Each item in a word of the affected translator is described in terms of size, displacement, auxiliary block word number, etc. The new contents of the translator words and items are described in terms of:

(a) truth value bits,
(b) format selector bits,
(c) data in the MSB (message storage buffer),
(d) data in the MSB auxiliary area.

The control pident RCTF (RC new pass translation format) PR-1A304 uses this data to build translation data from MSB data and the MSB auxiliary area data. The control pident RCCH (RC change pass translation) PR-1A305 uses it to reconstruct MSB data, MSB auxiliary area data, and truth value bits from old data in translations.

B. Change Translation Screening Table

2.20 The change translation screening table is used only on CHG or OUT messages during the reconstruction of keyword value from old translation data under control of the translation format table. This screening table is checked each time a keyword is reconstructed. Entries into this table can indicate any of the following:

- Old and new data can be compared (failure to match results in RC18 CHGER).
- The truth value bit can be unconditionally set for the keyword.

C. Change Keyword List

2.21 Entries into the change keyword list are used at the end of the change pass of the format table to move data from one keyword to another in preparation for a new pass of the format table and allows truth table bits for the moved data to be updated.

D. Change YES/NO Keyword List

2.22 Entries must be made into the change YES/NO keyword list for all YES/NO and NO/data keywords if CHG or OUT are valid forms for the message. The entries are used at the end of the CHG pass to correctly set the truth value bit for these keywords, as follows:

- If a value for the keyword was input, then the new value is used.
- If the keyword has not been input and the old data from translations indicates NO, then the truth value bit remains 0.
- If the keyword has not been input and the old data indicates YES or data, then the truth value bit is set and the old data value is entered in the MSB.

ERROR DICTIONARY SECTION

2.23 Following the data tables in a PR is the pident error dictionary. The error dictionary section is designed to be used in conjunction with the following three types of output messages:

- **RC18 INPUT**—An input error has been detected while the program was checking the keyword unit.
- **RC18 VALER**—A validity error has been detected—specifically, a fatal node has failed. Reference to the validity (tree) error dictionary is required to determine the error.
- **RC18 XLER**—A translation error has been detected:
(a) A nonexistent head table or translator
(b) An invalid address for a required pointer associated with an auxiliary block in translation
(c) Erroneous pointer to a word that should be located in a translation auxiliary block (lies beyond the end of the block).

2.24 The error dictionary section consists of some or all of the following parts, as appropriate for the particular message.

A. Keyword Table
2.25 The keyword table located in the error dictionary section contains all valid keywords for a message as well as the data type associated with each keyword (YES/NO, data/NO, data) and a brief description of the keyword. The keyword table will be located at the beginning of the error dictionary section.

B. Synonymous Keyword Table
2.26 As indicated by its name, the synonymous keyword table contains a list of keywords and their equivalents. The use of either of two equivalent keywords will be accepted by the ESS and mean the same thing. The synonymous keyword table follows the keyword table in the error dictionary section.

C. Keyword (Table) Error Dictionary
2.27 The keyword (table) error dictionary is referenced when the table identifier in the RC18 INPUT error message is KWT. The dictionary contains index, data type, and error description of associated keyword units by separate NEW, CHG, and OUT tables, as appropriate for the message.

D. Data Check Table Dictionary
2.28 The data check table dictionary contains indices, labels, and descriptions of each data check performed on associated keyword units. The tables are provided with prefixed NEW, CHG, and OUT to the table title, as appropriate for the message.

E. Validity (Tree) Error Dictionary
2.29 The validity (tree) error dictionary contains nodes, labels, and descriptions of each validity check performed. The tables are provided with prefixed NEW, CHG, and OUT to the table title as appropriate for the message. The validity (tree) error dictionary is referenced when a test established by the validity (tree) table has failed, resulting in an RC18 VALER output message.

F. Format Selector List
2.30 The format selector list contains a list of format selector names and their corresponding equivalencies. This error dictionary is generated only for format selectors of type NEW messages.

G. Validity Tree Diagram
2.31 The validity tree diagram (applicable to earlier generic programs only) provides a graphical description of valid keyword unit combinations for use in RC messages. The diagram uses node symbols to associate validity checking procedures with the cause and source of rejected input messages.

(a) The validity tree processing consists of performing Boolean functions upon previously defined truth values (keyword units, data checks, and validity tree nodes). The validity tree starts with a single word (12 bits) which defines the Boolean functions of the first node. The two functions of a node are:

(1) For the node to be true or false
   true: the node value is 1
   false: the node value is 0

(2) For the node to fail (and, in turn, the message) or not.

Where a node failure causes a message failure (rejection), it is called a fatal node. Where a node failure does not in itself result in an input message rejection, the node is called nonfatal.

(b) Table E lists the nodes and symbols descriptions used in graphical presentations of validity tree diagrams.

</table>

*These symbols were used on validity tree diagrams that appear in some message pident PSs. However, they are not reliable because they have not been updated, and are being removed from all PRs.

†args is arguments

‡Where the sum of args is the node value sum of the adjacent node located on all branches extending from a specified or referenced node.

**SHARED PIDENTS (RCTS AND RCSI)**

2.32 Shared pident RCTS (RC table subroutine) PR-1A319 and pident RCSI (RC shared information) PR-1A320 will sometimes be referenced while using other pidents in connection with problem analysis procedures.

2.33 Pident RCTS consist of special purpose subroutines and are used by RC message pidents—input (through pident RCSI), data check, and format—and by control pident RCWL (RC work list) PR-1A307. The subroutines provide functions that are too specialized to be handled efficiently by the macro languages of input, data check, and format.

2.34 Pident RCSI consists of five data tables accessed by several code pidents during RC message processing. The tables are as follows:

1. **Message Head Table:** The message head table contains a vector for each RC message pident. This table is used by control pident RCIG (RC and general control) PR-1A300.

2. **TAG and Assignment Table:** Each table entry provides the structure of a translator in terms of head table, number of bits in selector and index, primary translation word (PTW) and head table unassignment codes, and power of expansion values. These tables are used by routine RSGTG in control pident.
RSUB (RC subroutines) PR-1A309 when generating the program store address (TAG) of a translator.

(3) **Parameter Table:** The table is a transfer vector (TV) table for the parameters used in format checking of the keyword data. This table is used by control pident RCKI (RC keyword input) PR-1A302.

(4) **TV Table for Supplementary Input Tables:** Each table entry contains relocatable addresses of two supplementary input table assembly routines. The table is used when the entry in the keyword table of message pident points to a supplementary input table assembly routine in RCSL. This table is used by control pident RCKI.

(5) **Supplementary Input Table:** Each table entry consists of two or more 12-bit words that describe the data of a keyword and indicate whether to store the data in the MSB or MSB auxiliary area. Any of the RC message pidents can point to entries in this table. This table is used by control pident RCKI, using the TV table. Routines in this table may point directly to other routines in the table without having to refer back to the TV table.

### 3. TTY ACKNOWLEDGMENT (TACK) SYSTEM RESPONSE

**3.01** A TACK is an *immediate* response from the ESS after a specific input control character is received. The term immediate means that no other output can intervene. There are seven TACK categories:

1. Acceptable
2. Line Error
3. Message Error
4. Busy
5. Invalid Heading
6. Internal Program Error
7. Timeout

**3.02** Acceptance of an input is indicated either by a carriage return and line feed or a printed OK immediately following an input control character. A carriage return and line feed occurs following an input check (/), a line cancel (#), or a message cancel (&) character. An OK is printed immediately following an end-of-message (! or .) or an end-of-segment (%) character. The carrier return and line feed or OK indicate that the system is available for use, that no format errors were detected in the input, and that the information is entered into the system as instructed. In the case where a line cancel(#) or message cancel(&) character was inputted, the acceptable TACK response indicates that the required action has been taken. Examples of the acceptable TACK follows:

```
RC:LINE:
ORD 4804

CODE 2.DGS 6247230%OK
CODE 3.DGS 6248588!OK
RC18 12 5 ACPT
3/26 10:25
```
B. Line Error TACK

3.03 The line error TACK is printed immediately following the input check character (/) and the end-of-segment character (%) in the following form:

\[ aa = \text{Two letter TACK code indicating type of error detected (Table F)} \]

\[ bb = \text{Character (column) number, in octal, of the first character which may be in error. The character (column) spaces of the printout line are numbered from left to right, including spaces, beginning with 1.} \]

Upon determining the error, the erroneous input line can be retyped correctly into the system without affecting the preceding portion of the message. Examples of line error TACK are shown below:

```
RC:LINE,OUT:/
ORD 1211/
TN 922165/MD 12
```

(more decimal digits expected in TN)

```

<td>00000005</td>
<td>Segmenting illegal in this message</td>
</tr>
<tr>
<td>YN</td>
<td>00000022</td>
<td>Invalid data for YES/NO keyword</td>
</tr>
</tbody>
</table>

* A correctable error TACK consists of one of these codes followed by a 2-digit decimal column number of the error.
C. Message Error TACK (ER)

3.04 ER is the message error TACK and is printed immediately following the ! (end of message symbol) or the % (end of segment symbol). The ER TACK indicates that a noncorrectable error is contained in the message and that the entire message or message segment is removed from the system. The message must be reinputted after correction as indicated by the RC18 message which follows the ER. Examples of the ER TACK follow:

```
RC:LINE:
ORD 3504
TN 9620400
OE 02317101

6/11 5:29
```

D. Busy TACK (BUSY)

3.05 The BUSY TACK is printed immediately following the !, /, and % input characters. This TACK indicates that the recent change programs are busy on another channel and that the input must be repeated until an OK TACK is printed. An example of the BUSY TACK message is shown below:
E. Invalid Heading TACK (?IH)

3.06 The ?IH is the invalid heading TACK and is printed immediately following a / input character on the first line of a message indicating that an error has been detected in the heading line. Upon correction of the error, the heading line must be reinputted. An example of the ?IH TACK is shown below:

RC:LINE:/?IH
(Line misspelled)

F. Internal Program Error TACK <$INTERR$>

3.07 <$INTERR$> is the internal program error and is printed immediately following the !, /, and % input characters. The <$INTERR$> TACK notifies the operator that the program has an internal error and the raw data dumps provided in the RC16 messages can be analyzed to determine the program error. The input message cannot be processed until the program error is corrected. An example of the <$INTERR$> TACK follows:

RC:LINE:
ORD 10
MLH 355
OE 00406501
LCC RXR
CTX 2
TN 8941581
STAH
FREE
MSN 100407<$INTERR$>

G. Timeout TACK <$TIMEOUT$>

3.08 The <$TIMEOUT$> TACK is printed immediately following an IOT character (except ! and .) in a message that is typed into the system after 45 seconds has elapsed since the last character was typed, or if a tape input is used and the tape has been stopped for 45 seconds. It is necessary to reinput the entire message. An example of the <$TIMEOUT$> TACK is shown below:

RC:LINE:
ORD 10
MLH 355
OE 00406501
LCC RXR
CTX 2
TN 8941581
STAH
FREE
MSN 100407<$TIMEOUT$>
4. TTY OUTPUT MESSAGES FOLLOWING THE TACK

4.01 The output message (OM) following the TACK of an RC input message is an RC18 or an RC16 output message. These OMs may indicate acceptance of an input message, may explain errors detected in the input message, or may provide a series of data dumps to analyze problems arising from program errors.

A. RC18 Output Message

4.02 Almost all output messages encountered are RC18 messages. An RC18 message may indicate acceptance of an RC input message, or provide data resulting from successful execution of particular messages. Other RC18 messages provide coded data for error diagnosis and/or identification of error sources.

4.03 The RC18 output message consists of 21 types which fall into 5 categories as follows:

<table>
<thead>
<tr>
<th>RC18 MESSAGE TYPE</th>
<th>CATEGORY</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACPT</td>
<td>Nonerror</td>
</tr>
<tr>

</tr>
</tbody>
</table>

Notes: RC18 output message types are explained in Table G.

Note: RC18 output message types are explained in Table G.

4.04 The format of an RC18 message and the associated explanation are as follows:

<table>
<thead>
<tr>
<th>MESSAGE INDEX</th>
<th>ORDER NUMBER</th>
<th>RC18 MESSAGE TYPE</th>
</tr>
</thead>
<tbody>
<tr>
<td>RC18 ŭi</td>
<td>ŭi</td>
<td>ŭi ŭt ŭt ŭt ŭt ŭt</td>

</table>

*Only the 1st unit appears for RC:NOCNOG and RC:DAMSK messages. For RC:NOCNOG the 1st unit will be the number group (NOG). For RC:DAMSK the 1st unit will be the mask block index (MBI). These messages will then be followed by a standard RC18 ACPT message.*

+Only the 1st and 2nd units appear for RC:PSBLK and RC:SUBTRAN messages using keywords LNRG, LNLG14, or LNLG23. In all other RC:SUBTRAN messages, two RC18 INFO messages appear automatically: 1st and 2nd units appear in the 1st RC18 INFO message and the 3rd unit appears in the 2nd RC18 INFO message. These messages will then be followed by a standard RC18 ACPT message.

B. RC18 Interpretation Procedure

4.05 The meaning of an RC18 output message may be determined in the following manner:

1. The message index \( (i'i) \) is used to identify the message by using Table B.

2. The order number of the associated RC input is specified in the location.

3. The message type \( (tttt) \) is explained in Table G.

4. If the message type is one of the applicable error types, data unit(s) will identify the cause(s) of the system rejection by use of Table G. If the message type is INFO, the data units will specify information concerning the memory storage area for the RC input as specified in Table G.

C. ACPT-Type RC18 Message

4.06 The ACPT message indicates that the input message was accepted and executed by the system as specified. An example follows:

```plaintext
RC:LINE;OUT:
ORD 4611
TN 9221554!OK
```

```plaintext
RC18 0 4611 ACPT
6/5 17:58
```

</tbody>
</table>

**Note 1:** Note that 70 is the RC code for RUBOUT, X OFF, VT and FORM. All are ignored, so there is no reason to distinguish between them.

**Note 2:** Any ASCII code not used by the RC program is converted to RC code 77.

**Note 3:** This combination is used to indicate an input character parity error.
D. BRKRC-Type RC18 Message

4.07 The BRKRC message indicates that a manual break of interruption of the input program was received by the system. This would normally occur as a result of depressing the BREAK key on any input keyboard connected to that channel. The input message must be correctly reinputted into the system. The following example illustrates the use of the BREAK key following the ! in the first message and its correct reinput:

RC:LINE:
ORD 1505
TN 9228950
OE 01014501
LCC 1R!
?

RC18 0 1505 BRKRC
5/30 11:19

F. DELAY-Type RC18 Message

4.09 The DELAY message indicates an error in a delayed input message which falls into three categories as follows:

1. SEG—A segmented input message (containing more than one segment using a % character) cannot be delayed.

2. ORD—An incorrect or no order number was in the input message.

3. ASN—An assignment error either by inputting a delay order number that is already in the system or inputting an activation or deactivation order for a delay order number which does exist in the system.

The corrected message must be inputted. Examples of the DELAY message follow:

RC:SCLIST;DELAY:
ORD 26
TN 7273081
ADN 3
DGS 5843742%ER

RC18 12 26 SEG
7/24 9:28
(Segmented Message)

RC:LINE;OUT;DELAY:
TN 8684730
CTX 7!ER
RC18 0 0 DELAY
6/6 10:27
(No Order Number)

E. CHGER-Type RC18 Message

4.08 The CHGER message indicates that there is a discrepancy between a keyword of a CHG or OUT input message and the existing translation information in the system. This could be an error such as attempting to CHG or OUT a feature on a line which does not exist in the translation information for that line or inconsistency in input information. An example of a CHGER message follows:

RC:LINE;OUT:
ORD 12
TN 8938338
OE 07402502!ER

RC18 0 12 CHGER
MSB 00000035
3/28 16:51
G. INED-Type RC18 Message

4.10 The INED message indicates an input editor error. The output message contains four data units explaining the error and its location by use of Tables G and H. Correct any errors present and reinput message. An example follows with an input character parity error and reinput:

RC:LINE:
ORD 4722
TN 9226370
OE 03006202
LCC 1MR!ER
RC18 0 4722 INED
IC 00000077 LC 00040003 INP 0000017 STA 0000003
6/5 18:16

RC:LINE:
ORD 4722
TN 9226370
OE 03006202
LCC 1MR!OK
RC18 0 4722 ACPT
6/5 18:17

H. INFO-Type RC18 Message

4.11 The INFO message specifies storage location for the input message in up to three data units. (See Table G). This output message is only used with the RC:NOCNOG, RC:DAMSK, RC:PSBLK, and RC:SUBTRAN input messages. As examples the following are presented:

RC:DAMSK:
GSZ 154
TERS(10, 11, 12, 13, 14, 15)%OK
TERS(16, 17, 18, 19, 20, 21, 22, 23, 24, 25)!OK
RC18 58 0 INFO
MBI 00000035
3/20 11:06
RC18 58 0 ACPT
3/20 11:06

RC:PSBLK:
ORD 131
NEW R12!OK
RC18 8 131 INFO ADD 02163432 OCT 000014
6/13 3:14
RC18 8 131 ACPT
6/13 3:14
I. INPUT-Type RC18 Message

4.12 The INPUT message indicates that an error was made in the input message to the system. The following procedure should be used to locate and analyze the error:

1. Determine which RC message is in error by using the message index \( i_i \) and, if specified, the order number \( r_i \) in the RC18 message. Refer to Table B for the listing of RC message indexes. For those messages identified by error code DE, KI, KT, LP, RP, or SI the error index \( 3r \) should be ignored. The line and column information can still be used to locate the characters in error and, usually, the definition in Table F of the error code is self-explanatory.

2. Using Table G, locate the INPUT type message. Convert the second data unit octal line and column (character) number \( zzzzzzzz \) to decimal numbers. (See Fig. 3.) Use the decimal line and column numbers to locate the characters in error. Begin line counting with the heading line as number 1. Count column (character) numbers from left to right, including spaces, beginning with 1. The error code \( xxx \) (Table F) defines the type of error.

3. Determine the input message error and the corrections necessary to input an acceptable message.

4. Reinput the corrected RC message for acceptance by the system.

5. If the second data unit error code \( xxx \) is not self-explanatory, determine by using the 3rd data unit which input table error dictionary should be used to obtain more details.

   • If the 3rd data unit \( xxx \) is KWT, locate the keyword table error dictionary associated with the applicable input message program PR-(Table G).

   • If the 3rd data unit \( xxx \) is SIT, locate the supplementary input table error dictionary in PR-1A320 (pident RCSI).

The 3rd data unit's octal number \( zzzzzzzz \) is the index number into the appropriate error dictionary. The error dictionary will then provide data types and a more detailed error description. Table I lists the codes and symbols used in the data type column of an error dictionary and a description of these codes.

An example of an INPUT output message containing an incorrect TN follows:

```plaintext
RC: LINE:
ORD 0005
OE 0000003
TN 5733141ER

RC18 0 5 INPUT

J. MTYPE-Type RC18 Message

4.13 The MTYPE message indicates an error in the message type identifier which is located on the RC heading line in the right subfield of the identification (2nd) field (usually NEW, CHG or OUT). Reinput corrected message. An example follows with an incorrect ICP input:
### TABLE I

INPUT DATA TYPE SYMBOLS IN PROGRAM LISTINGS

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>D</td>
<td>Decimal digit (0-9)</td>
</tr>
<tr>
<td>O</td>
<td>Octal digit (0-7)</td>
</tr>
<tr>
<td>B</td>
<td>Binary digit (0-1)</td>
</tr>
<tr>
<td>C</td>
<td>Alphabetic character (A-Z)</td>
</tr>
<tr>
<td>A</td>
<td>Alphanumeric character (A-Z and 0-9)</td>
</tr>
<tr>
<td>CHAR</td>
<td>Also used for character when character can be alphabetic or numeric</td>
</tr>
<tr>
<td>...D</td>
<td>Variable number of decimal digits with leading zeros optional</td>
</tr>
<tr>
<td>...O</td>
<td>Variable number of octal digits with leading zeros optional</td>
</tr>
<tr>
<td>N</td>
<td>Digit from 2 to 9 (used as first digit of office code; example, NXX)</td>
</tr>
<tr>
<td>X</td>
<td>Digit from 0 to 9 (used as second and third digits of office code; example, NXX)</td>
</tr>
<tr>
<td>/</td>
<td>Exclusive OR operation. Example, YES/NO means type YES or NO.</td>
</tr>
<tr>
<td>'</td>
<td>Denotes a literal to be inputted. Example, 'RG' means must input RG.</td>
</tr>
<tr>
<td>/</td>
<td>Encloses an optional character. Example, [C] means alphabetic character is optional.</td>
</tr>
<tr>
<td>&lt;=</td>
<td>Less than or equal</td>
</tr>
<tr>
<td>, , , ,</td>
<td>Stands for the word through when used in an expression that defines a series where only the first and last members of the series are stated in the expression, such as MIN1 , , , MIN5</td>
</tr>
</tbody>
</table>

**Note:** These codes and symbols are used to describe keyword data in the keyword lists, the keyword table error dictionaries, and the supplementary input table error dictionary.
SECTION 231-118-320

4.14 The NOCR message indicates that there was no CR and NL following the heading line (first two fields). Reinput message correctly. An example follows:

RC:LINE;ICP:
ORD 412
IN 5735030
OE 06410702!ER

RC18 0 0 MTYPE
7/3 6:29

K. NOCR-Type RC18 Message

4.17 Validity errors (VALER) are detected by *programmed checks* that are performed to assure that the combination of the input keywords and the keywords data are consistent with the existing data base (translation memory). These validity errors appear as *fatal node failures* and are reported by the VALER type RC18 output message (Table G).

4.18 Three examples of errors which would be reported as validity errors are:

1. Attempting to assign a line already assigned or to unassign a line which is not assigned

   RC:LINE;OUT:ORD 2333
   TN 9221914!ER

2. Attempting to assign an unworkable combination of features to a line

   RC18 0 2333 NOCR
   7/19 14:01

3. Attempting to use RC CHG messages for transitions not permitted by the system.

4.19 An example of a VALER message follows:

RC:LINE;OUT:
ORD 1099
TN 9223732!ER

RC18 0 1099 VALER
4/11 9:08

RC18 53 0 OBJT
4/11 9:08

M. PUNCT-Type RC18 Message

4.16 The PUNCT message indicates a punctuation error in the heading line (first message line). Correct error and reinput message. An example (omitted colon) follows:

RC:LINE;OUT
ORD 33
TN 5349745
OE 02114300!ER

RC18 0 0 PUNCT
7/24 14:54

In this example, the PR-1A336 Change Validity (Tree) Error Dictionary, RC:LINE; lists the error description of Node 245 as TN must be assigned.

O. XLER-Type RC18 Message

4.20 The XLER message reports that instructions contained in the RC input message cannot be accomplished with the existing system translation data, which could be inconsistent input data (Table G). Such inconsistencies may also result in a VALER or RC16 INTERR output message. The RC TAG and assignment error dictionary (PR-1A320) list three types of translation errors reportable by the XLER output message as follows:
4.21 The UNA-type translation output message indicates an error in input data or a procedural error in the sequence of related input messages.

4.22 The ALG- and AAD-type of translation output messages indicate an error in translation data that require further analysis.

4.23 The remainder of the RC TAG and assignment error dictionary provides tabulated information from the TAG and assignment table in pident RCSI (PR-1A320) that identifies all translations. The principal use of the tabulations is to identify a translator that is associated with a problem by using the primary TAG assignment (PTA) index provided in the RC18 output message.

4.24 An example of the XLER message follows:

```
RC:LINE;OUT:
ORD 12
TN 5346256
OE 00114320!ER
RC18 0 12 XLER
PTA 00000000 CON 00257027 TAG 02547225
ALG 31200444 TIN 17400406 #10000000
7/10 6:40
```

4.25 The RC16 INTERR output message is explained in paragraphs 4.30 through 4.38.

4.27 The PRTER RC18 message results from a print call error where the print routine expects a particular character(s) for printing but the character is not received (Table G). INFO RC18 messages that provide information associated with an accepted input message but did not provide the expected information to the print routine is one situation where a PRTER message results. Parity check failures are also causes for the PRTER message. Assistance should be requested from the local TAC, SCCS, or from the PECC location.

4.28 The TABER RC18 message results from a table specification error, such as an invalid RC18 message (Table G). An invalid message is generated when an incorrect value is loaded into the buffer for printing. A typical cause for TABER messages is that an associated table is expected to contain particular information, but does not. Assistance should be requested from the local TAC, SCCS, or from the PECC location.

4.29 RC16 output messages indicate that the system has encountered problems which apparently are caused by internal errors in the program. Detection of such an error results in a series of seven RC16 INTERR message segments which consists of a varying quantity of eight digit numbers. The segments consists of:
These words are data dumps which should provide information to determine the problems encountered in the system program. An example of the RC16 message follows:

<table>
<thead>
<tr>
<th>RC16 INTERR MESSAGE NUMBER</th>
<th>QUANTITY OF WORDS</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. CC Registers</td>
<td>6</td>
</tr>
<tr>
<td>2. States &amp; Pointers</td>
<td>10</td>

R. RC16 Interpretation Procedure

4.30 RC16 message data analysis requires ability to interpret data in the program listings.

First RC16 INTERR Printout

4.31 The first RC16 INTERR printout message segment consists of six words that provide the octal contents of central control registers at the time an internal error is detected. The sequence of the register content words for are:

```
FFFFFFFF KKKKKKKK LLLLLLLL XXXXXXXX YYYYYYYY ZZZZZZZZ
```

The L register word is most important because it contains the return address and thus provides the code pident location at which the error was detected. By proceeding to the location in the specified pident pointed to by the L register, the description of the reason for the INTERR output message is provided. Also, the same description allows interpretation of the other associated registers, as well as the use of the remaining segments of the message.

4.32 Although the contents of the central control registers vary in accordance with the specific INTERR call, the programming requirements used for the RC system permit some general statements about the probable content of the registers.

(a) **L Register**: Address of the client program that called the INTERR routine. The correct interpretation of the location pointed to by the L register is the most critical step in the interpretation of the message printout segments. In some instances, the L register word provides all required information. In other instances, some or all of the remaining printout segments must be interpreted. The L register’s use within the control pident RSUB is of special importance because RSUB consists of shared subroutines referenced by other code pidents. For this case, L normally indicates the error identity, but does not specify when or the location where the error occurred. For this case, reference is required to the state words and push down scratch to determine the error location.

(b) **X Register**: In control pidents RCKI, RCVC, RCFI, RCCH, or RCTF, the X register typically contains the 12-bit address in the table where the INTERR error occurred. Thus, isolation of the error is permitted to a 12-bit word in the message pident.

(c) **F, K, Y, and Z Registers**: Use the L register and pident to determine contents.

Second RC16 INTERR Printout

4.33 The second RC16 INTERR printout message segment consists of state and pointer words. The following information shows ten call store words starting with address 17406 through 17417.

```
R2PSW1 R2PSW2 R2PDS R2NAPDS R2MSB R2MSBAUX R2NAMSBA
R2WL R2NAWL R2EWL
```
The four words that provide information of the greatest significance are as follows:

- R2PSW1 Code pident currently in control
- R2NAPDS Points to the next available word of the push down scratch
- R2NAMSBA Specifies next available word in the MSB auxiliary area
- R2NAWL Specifies the next available work list location.

Where the error is identified but not the error location, use C(R2NAPDS) -1 to C(R2PDS), which is all used push down scratch, to construct a history of events leading up to the internal error. Since the scratch system provides client addresses and in some cases the contents of the central control registers when a client called a subroutine, the problem can be identified by working backward from the last used push down scratch entry at C(R2NAPDS) -1.

**Note:** The R2PDSMSB (points to RC PDS and MSB) program store location provides the size of the push down scratch area (R2PDS and R2NAPDS-128 words) and the size of the message storage buffer (R2MSB) and its associated message buffer auxiliary area (R2MSBAUX and R2NAMSBA) in the left half of the program store word and the starting address of the call store block in the right half of the program store word. The call store block is used exclusively by the RC message interpretation.

**Third RC16 INTERR Printout**

**4.34** The third RC16 INTERR printout message segment provides five input control words located in call store with addresses starting with 17450 as follows:

- 17450 ASCII character last processed
- 17451 Input editor state
- 17452 Line buffer unload pointer
- 17453 Current line
- 17454 Current column.

**4.35** The ASCII to RC character table in pident RCIE is used to convert the 7-bit ASCII character code received on the I/O channel into the 6-bit character code used internally by the RC programs.

**4.36** The state table for input editor is used to obtain subroutine codes (index to ISUBRT) and next state index which points the program to the proper character subroutine for processing I/O characters.

**Fourth and Fifth RC16 INTERR Printout**

**4.37** The fourth and fifth RC16 INTERR printout message segments provide a Boolean history of input, data check, validity, and format selection of the RC input message. By inspecting the truth value table (fourth printout segment), keyword units that were received can determine which data checks were true, and which validity tree nodes were true. The format selector (fifth printout segment) provides the selected paths by using a format based on the input and translation data.

**Sixth and Seventh RC16 INTERR Printout**

**4.38** The sixth and seventh RC16 INTERR printout message segments provide a part of the 128-word push down scratch. The sixth segment prints the first 14 words of the 128-word push down scratch. The seventh segment prints 21 words: 14 words prior and seven words after R2NAPDS (second RC16 INTERR fourth word) which is located within the 128-word push down scratch. In some circumstances, T-READ procedures are required to determine additional words in the 128-word push down scratch.

**5. ABBREVIATIONS AND ACRONYMS**

**5.01** Table C and D provide a description of information fields located within the line format (Fig. 1) and the definition and reference tables (Fig. 2) which will not be included in the abbreviations. Other abbreviation items are as follows:

- AAD—Auxiliary block address invalid (auxiliary block does not exit)
- ACPT—Message accepted
- ADD—Address
AGN—Assignment
ALG—Auxiliary block length exceeded
ASCII—American Standard Code for Information Interchange
ASN—Assignment
BRKRC—Break received
CHGER—Change error
C/O—Change or out type message
CON—Contents
CR—Carriage return
DE—Data exceeds allocated buffer
DELAY—Error in delay message
DL—Data lower bound violated (data too small)
DS—Discrete data not valid (data does not equal any of the specific valid values)
DU—Data upper bound exceeded (data too large)
ER—Error
HTA—Head table address
I—Invalid backspace
IA—Invalid character—alphanumeric (letter or number) expected
IB—Invalid character—binary digit expected
IC—Illegal character
ID—Invalid character—decimal digit expected
IDX—Index
IM—Input message
IN—Invalid character—numeric digit expected
INED—Input editor error
INFO—Information (associated with execution of message)
INP—Input
INPUT—Input error
INTERR—Internal error
IO—Invalid character—octal digit expected
I/O—Input/Output
IS—Invalid character—range hyphen (-) or comma (,) expected
IT—Invalid TOUCH-TONE® digit
KI—Keyword invalid for this message
KR—Keyword repeated in message illegally
KT—Keyword unit termination invalid or necessary when expected
KU—Keyword unavailable because associated package not loaded
KW—Keyword
KWT—Keyword table
LC—Line column
LP—Left parenthesis missing
MB—More binary digits expected
MBI—Mask block index
MD—More decimal digits expected
MK—More keywords than permitted on one line
MO—More octal digits expected
MSB—Message storage buffer (a storage facility in the call store area)
MTYPE—Message type
NAUX—Not enough auxiliary block available
NAWL—Not enough available work list space
NEW—New
NL—New line (previously line feed)
NLLS—Not enough link list scratch available
NOCR—No carriage return after two fields of messages
NOG—Number group
NOPS—No program store block
NPRC—Not enough primary recent change registers available
OBJT—Message object identifier error
OCT—Octal
OM—Output message
ORD—Order number
PG—Program generic
Pidents—Program identification
PLUGF—Plug-up failure
PR—Program listing
PRTER—Print call error
PTA—Primary tag assignment
PTW—Primary translation word
PUNCT—Punctuation error in heading line
RC—Recent change
RCCH—Recent change pass translation format (PR-1A305)
RCDY—Recent change delay order (PR-1A308)
RCFI—Recent change format interpretation (PR-1A306)
RCIE—Recent change input editor (PR-1A301)
RCIG—Recent change initialization and general control (PR-1A300)
RCKI—Recent change keyword input (PR-1A302)
RCSI—Recent change shared information (PR-1A320)
RCTF—Recent change new pass translation format (PR-1A304)
RCTS—Recent change table subroutine (PR-1A319)
RSUB—Recent change subroutines (PR-1A309)
RCVC—Recent change validity check (PR-1A303)
RCWL—Recent change work list (PR-1A307)
RCxx—One pident per recent change input message. (See Table A)
RP—Right parenthesis missing
SCCS—Switching Control Center System
SE—Error detected by subroutine (see pident RCSI in PR-1A320 for more information)
SEG—Segmented
SI—Segmenting illegal in this message
SIT—Supplementary input table (PR-1A320)
SMB—Segmented
STA—State
SWAP—Switching Assembly Program
TABER—Table specification error (internal program error)
TAC—Technical assistance center
TACK—TTY acknowledgment
TAD—Table address
TAG—Address of primary translation word
TIN—Translation input
TTY—Teletypewriter
TV—Transfer vector table
UNA—Unassigned head table or translator
VALER—Validity error
XLER—Translation error
YN—Invalid data for YES/NO keyword
!—Exclamation point - end of message symbol
.—Period - end of non-RC message

%—Percent sign - execute and save common data
/—Slash - input check
$—Dollar sign - line cancellation
&—Ampersand - message cancellation.
