FEATURES
• Ultra-low power consumption, quiet, pumpless design
• Two digitally controlled, 256-position potentiometers
• Serial port provides means for setting and reading both potentiometers
• Resistors can be connected in series to provide increased total resistance
• 20-pin TSSOP package
• Resistive elements are temperature compensated to ±0.3 LSB relative linearity
• Standard resistance values:
  – DS1868-10 ~ 10kΩ
  – DS1868-50 ~ 50kΩ
  – DS1868-100 ~ 100kΩ
• +5V or ±3V operation
• Temperature: 0°C to 70°C commercial
  –40°C to 85°C industrial

DESCRIPTION
The DS1868 consist of two digitally controlled solid-state potentiometers. Each potentiometer is composed of 256 resistive sections. Between each resistive section and both ends of the potentiometer are tap points which are accessible to the wiper. The position of the wiper on the resistor array is set by an 8-bit value that controls which tap point is connected to the wiper output. Communication and control of the device is accomplished via a 3–wire serial port interface. This interface allows the device wiper position to be read or written.

Both potentiometers can be connected in series (or stacked) for an increased total resistance with the same resolution. For multiple device–single processor environments, the DS1868 can be cascaded or daisy chained. This feature provides for control of multiple devices over a single 3–wire bus.

The DS1868 is offered in three standard resistance values which include 10k, 50k, and 100k Ohm versions. The part is available in 16-pin SOIC (300 mil), 14-pin DIP, and 20-pin (173 mil) TSSOP packages. Both commercial and industrial temperature grades are also available.

OPERATION
The DS1868 contains two 256–position potentiometers whose wiper positions are set by an 8–bit value. These
two 8–bit values are written to a 17–bit I/O shift register which is used to store the two wiper positions and the stack select bit when the device is powered. A block diagram of the DS1868 is presented in Figure 1.

Communication and control of the DS1868 is accomplished through a 3–wire serial port interface that drives an internal control logic unit. The 3–wire serial interface consists of the three input signals: RST, CLK, and DQ.

The RST control signal is used to enable the 3–wire serial port operation of the device. The RST signal is an active high input and is required to begin any communication to the DS1868. The CLK signal input is used to provide timing synchronization for data input and output. The DQ signal line is used to transmit potentiometer wiper settings and the stack select bit configuration to the 17–bit I/O shift register of the DS1868.

Figure 9(a) presents the 3–wire serial port protocol. As shown, the 3–wire port is inactive when the RST signal input is low. Communication with the DS1868 requires the transition of the RST input from a low state to a high state. Once the 3–wire port has been activated, data is entered into the part on the low to high transition of the CLK signal inputs. Three–wire serial timing requirements are provided in the timing diagrams of Figure 9(b),(c).

Data written to the DS1868 over the 3–wire serial interface is stored in the 17–bit I/O shift register (see Figure 2). The 17–bit I/O shift register contains both 8–bit potentiometer wiper position values and the stack select bit. The composition of the I/O shift register is presented in Figure 2. Bit 0 of the I/O shift register contains the stack select bit. This bit will be discussed in the section entitled Stacked Configuration. Bits 1 through 8 of the I/O shift register contain the potentiometer–1 wiper position value. Bit 1 will contain the MSB of the wiper setting for potentiometer–1 and bit 8 the LSB for the wiper setting. Bits 9 through 16 of the I/O shift register contain the value of the potentiometer–0 wiper position with the MSB for the wiper position occupying bit 9 and the LSB bit 16.
Transmission of data always begins with the stack select bit followed by the potentiometer–1 wiper position value and lastly the potentiometer–0 wiper position value.

When wiper position data is to be written to the DS1868, 17 bits (or some integer multiple) of data should always be transmitted. Transactions which do not send a complete 17–bits (or multiple) will leave the register incomplete and possibly an error in the desired wiper positions.

After a communication transaction has been completed the RST signal input should be taken to a low state to prevent any inadvertent changes to the device shift register. Once RST has reached a low state, the contents of the I/O shift register are loaded into the respective multiplexers for setting wiper position. A new wiper position will only engage after a RST transition to the inactive state. On device power–up, wiper position will be random.

STACKED CONFIGURATION
The potentiometers of the DS1868 can be connected in series as shown in Figure 3. This is referred to as the stacked configuration and allows the user to double the total end–to–end resistance of the part. The resolution of the combined potentiometers will remain the same as a single potentiometer but with a total of 512 wiper positions available. Device resolution is defined as \( R_{TOT}/256 \) (per potentiometer); where \( R_{TOT} \) equals the total potentiometer resistance.

The wiper output for the combined stacked potentiometer will be taken at the \( S_{OUT} \) pin, which is the multiplexed output of the wiper of potentiometer–0 (W0) or potentiometer–1 (W1). The potentiometer wiper selected at the \( S_{OUT} \) output is governed by the setting of the stack select bit (bit 0) of the 17–bit I/O shift register. If the stack select bit has value 0, the multiplexed output, \( S_{OUT} \), will be that of the potentiometer–0 wiper. If the stack select bit has value 1, the multiplexed output, \( S_{OUT} \), will be that of the potentiometer–1 wiper.

STACKED CONFIGURATION Figure 3

![Stacked Configuration Diagram](image-url)
CASCADE OPERATION
A feature of the DS1868 is the ability to control multiple devices from a single processor. Multiple DS1868s can be linked or daisy chained as shown in Figure 4. As a data bit is entered into the I/O shift register of the DS1868 a bit will appear at the COUT output after a minimum delay of 50 nanoseconds. The stack select bit of the DS1868 will always be the first out the part at the beginning of a transaction. The COUT pin will always have the value of the stack select bit (b0) when RST is inactive.

CASCADE MULTIPLE DEVICES

The COUT output of the DS1868 can be used to drive the DQ input of another DS1868. When connecting multiple devices, the total number of bits transmitted is always 17 times the number of DS1868s in the daisy chain.

An optional feedback resistor can be placed between the COUT terminal of the last device and the first DS1868 DQ input thus allowing the controlling processor to read, as well as, write data, or circularly clock data through the daisy chain. The value of the feedback or isolation resistor should be in the range from 2K to 10K ohms.

When reading data via the COUT pin and isolation resistor, the DQ line is left floating by the reading device. When RST is driven high, bit 17 is loaded into the first position of the I/O shift register and bit 16 becomes present on COUT and DQ of the next device. After 17 bits (or 17 times the number of DS1868s in the daisy chain), the data has shifted completely around and back to its original position. When RST transitions to the low state to end data transfer, the value (the same as before the read occurred) is loaded into the wiper–0, wiper–1, and stack select bit I/O register.

ABSOLUTE AND RELATIVE LINEARITY
Absolute linearity is defined as the difference between the actual measured output voltage and the expected output voltage. Figure 5 presents the test circuit used to measure absolute linearity. Absolute linearity is given in terms of a minimum increment or expected output when the wiper is moved one position. In the case of the test circuit, a minimum increment (MI) or one LSB would equal 5/256 volts. The equation for absolute linearity is given as follows:

(1) ABSOLUTE LINEARITY
\[ AL = \frac{V_o(\text{actual}) - V_o(\text{expected})}{\text{MI}} \]

Relative Linearity is a measure of error between two adjacent wiper position points and is given in terms of MI by equation (2).

(2) RELATIVE LINEARITY
\[ RL = \frac{V_o(n+1) - V_o(n)}{\text{MI}} \]

Figure 6 is a plot of absolute linearity and relative linearity versus wiper position for the DS1868 at 25°C. The specification for absolute linearity of the DS1868 is ±0.75 MI typical. The specification for relative linearity of the DS1868 is ±0.3 MI typical.

TYPICAL APPLICATION CONFIGURATIONS

Figures 7 and 8 show two typical application configurations for the DS1868. By connecting the wiper terminal of the part to a high impedance load, the effects of the wiper resistance is minimized, since the wiper resistance can vary from 400 to 1000 ohms depending on wiper voltage. Figure 7 presents the device connected in a variable gain amplifier. The gain of the circuit on Figure 7 is given by the following equation:

\[ A_V = \frac{256}{256 - n} \quad \text{where} \quad n = 0 \text{ to } 255 \]

Figure 8 shows the device operating in a fixed gain attenuator where the potentiometer is used to attenuate an incoming signal. Note the resistance R1 is chosen to be much greater than the wiper resistance to minimize its effect on circuit gain.

### Notes:

1. All voltages are referenced to ground.
2. Resistor inputs cannot exceed $V_B - 0.5V$ in the negative direction.
3. Capacitance values apply at 25°C.
4. Absolute linearity is used to determine wiper voltage versus expected voltage as determined by wiper position. Device test limits ±1.6 LSB.
5. Relative linearity is used to determine the change in voltage between successive tap positions. Device test limits ±0.5 LSB.
6. Typical values are for $T_A = 25$°C and nominal supply voltage.
7. –3 dB cutoff frequency characteristics for the DS1868 depend on potentiometer total resistance: DS1868–010; 1 MHz, DS1868–050; 200 KHz; and DS1868–100; 80 KHz.
8. $C_{\text{OUT}}$ is active regardless of the state of RST.
9. $V_{\text{REF}}$ = 1.5 volts.
10. See Figure 9(a), (b), and (c).
12. Supply current is dependent on clock rate (see Figure 11).
13. See Figure 10.
14. Standby currents apply when RST, LLIC, DQ are in the low state.
15. When biasing the substrate minimum $V_B = -3.0V \pm 10\%$ and maximum $V_{\text{CC}} = 3.0V \pm 10\%$.
