Monolithic Multiplier/Detector

GENERAL DESCRIPTION

The XR-2228 is a monolithic multiplier/detector circuit especially designed for interfacing with integrated phase-locked loop (PLL) circuits, to perform synchronous AM detection and triangle-to-sinewave conversion. It combines a four-quadrant analog multiplier (or modulator) and a high-gain operational amplifier in a single monolithic circuit.

As shown in the equivalent schematic diagram, the four-quadrant multiplier section is designed with fully differential X- and Y-inputs and differential outputs. For maximum versatility, the multiplier and the operational amplifier sections are not internally connected. The operational amplifier can also function as a pre-amplifier for low-level input signals, or as a post-detection amplifier for synchronous demodulation, phase-detection or for sine-shaper applications.

FEATURES

Independent Multiplier and Op Amp Sections
Differential X and Y Inputs
Interfaces with all PLL and VCO Circuits
Wide Common Mode Range
Wide Transconductance Bandwidth (100MHz, Typ.)
Wide Supply Voltage Range (±4.5V to ±16V)

APPLICATIONS

Phase-Locked Loop Design
Phase Detection
Synchronous AM Detection
AM Generation
Triangle-to-Sinewave Conversion
Frequency Translation

ABSOLUTE MAXIMUM RATINGS

Power Supply ±18 Volts
Power Dissipation
Ceramic Package 750mW
Derate above +25°C 6mW/°C
Plastic Package 625mW
Derate above +25°C 5mW/°C
Storage Temperature Range -65°C to +150°C

ORDERING INFORMATION

Part Number Package Operating Temperature
XR-2228CN Ceramic 0°C to +70°C
XR-2228CP Plastic 0°C to +70°C

SYSTEM DESCRIPTION

The XR-2228 multiplier/detector contains a four quadrant multiplier and a fully independent operational amplifier. The four quadrant multiplier has fully differential X and Y inputs and outputs. Both inputs have 3MHz dynamic response and 100MHz transconductance bandwidth. The operational amplifier features high gain and a large common mode range. The device is powered by 4.5V to 16V split supplies.

For higher frequency applications, consider the XR-2208.
### ELECTRICAL CHARACTERISTICS

#### Test Conditions: Supply Voltage = ±15V, $T_A = 25^\circ C$, unless otherwise specified.

Note 1: $T_{LOW} = 0^\circ C$, $T_{HIGH} = +70^\circ C$ for XR-2228C; not tested in production

**CAUTION:** When using only the op amp or only the multiplier section of the XR-2228, the input terminals to the unused section must be grounded. Thus, when using the multiplier section alone, ground pins 13 and 14; when using the op amp section alone, ground pins 2, 3, 4 and 5.

Figure 3. Test Circuit for Feedthrough Measurement. X-Input Feedthrough = $V_z$ with $S_1$ open, $S_2$ closed. Y-Input Feedthrough = $V_z$ with $S_1$ closed, $S_2$ open.

Figure 4. Test Circuit for Multiplier Small-Signal Bandwidth for X-Input (For Y-Input, reverse connections between Pins 2 and 5)
SCALE FACTOR, K: The constant of proportionality that relates the multiplier output to the X and Y inputs. If the offset terms are neglected, the multiplier output, \( V_z \), is related to the X and Y inputs as \( V_z = K(V_x \cdot V_y) \). The scale factor \( K \) has the dimensions of \((\text{volts})^{-1}\) and can be adjusted externally.

In most arithmetic applications, the multiplier and op amp sections of the XR-2228 are interconnected as shown in Figure 14. In such applications, the overall scale factor \( K \) can be written as:

\[
K = \frac{V_o}{V_x V_y} \cdot \frac{V_z}{V_o}
\]

where \( K_m \) is the gain constant of the multiplier section, and \( K_a \) is the gain of the op amp stage in Figure 14. \( V_o \) is the multiplier output across pins 1 and 16, and \( V_z \) is the op amp output at pin 11. With reference to Figure 14, the gain constants can be expressed as:

\[
K_m = \frac{25}{R_x R_y} \text{(volts)}^{-1}; \quad K_a = \frac{R_i}{6 + R_i}
\]

where all resistors are in kilo-ohms.

Thus, the overall scale factor \( K \) can be adjusted by varying \( R_x, R_y, R_i \). For fine adjustment of the scale factor, \( K \), an additional potentiometer can be included in the circuit, as shown in Figure 14.

INPUT DYNAMIC RANGE: The maximum peak signal which can be applied to the X or Y inputs for a given supply voltage without impairing linearity. (See Figure 10).

MULTIPLIER BANDWIDTH: Depending on the particular application, a different definition of "multiplier bandwidth" may be used. The most commonly accepted definitions are:

a) **3-dB Bandwidth**: Frequency where the multiplier output is 3-dB below its low frequency \((f = 20\,\text{Hz})\) level.

b) **3° Phase Shift Bandwidth**: Frequency where the net phase shift across the multiplier is equal to 3°.

c) **1% Absolute Error Bandwidth**: Frequency where the phase vector error between the actual and ideal output vectors is equal to 1%. This frequency is reached when the net phase shift across the multiplier is equal to 0.01 radian or 0.57°.

d) **Transconductance Bandwidth**: Frequency where the transconductance of the multiplier drops 3-dB below its low frequency value. This bandwidth defines the frequency range of operation for phase-detector and synchronous AM detector applications.

DESCRIPTION OF CIRCUIT CONTROLS

MULTIPLIER INPUTS (Pins 2, 3, 4 and 5): These four terminals provide the differential inputs to the X- and Y-sections of the multiplier, respectively. The output will be a linear product of the two voltages, Vx and Vy, applied differentially across pins (2,3) and (4,5). Typical input bias current at the multiplier inputs is approximately 3μA, for each of the four inputs. In circuit applications requiring single-ended, rather than differential, input signals, pins 3 and 4 can be shorted together and connected to a common bias point.

MULTIPLIER OUTPUTS (Pins 1 and 16): The differential output voltage, V_o, across these terminals is proportional to the linear product of voltages Vx and Vy applied to the inputs. V_o can be expressed as:

\[ V_o = \left( \frac{25}{R_x R_y} \right) (V_x V_y) \]
where all voltages are in volts and the resistors are in kΩ. $R_x$ and $R_y$ are the gain control resistors for X and Y sections of the multiplier.

The common-mode dc potential at the multiplier outputs is approximately 3 volts below the positive supply.

In most analog computation operations, such as multiplication, division, etc., pins 1 and 16 are dc coupled to the op amp inputs (pins 13 and 14). The final output, $V_z$, is then obtained from the op amp output at pin 11, as shown in Figures 14 and 15.

**X AND Y GAIN ADJUST (Pins 6, 7, 8, 9):** The gains of the X and Y sections of the multiplier are inversely proportional to resistors $R_x$ and $R_y$ connected across the respective gain terminals. The multiplier conversion gain, $K_m$, can be expressed as:

$$K_m = \frac{25}{R_x R_y} \text{ (volts)}^{-1}$$

where $R_x$ and $R_y$ are in kΩ.

**X AND Y OFFSET ADJUST (Pins 7 and 8):** Two of the gain-control terminals, pins 7 and 8, are also used for adjusting X and Y offsets. Figure 13 shows the typical adjustment circuitry which can be connected to these pins to null-out input offsets.

**OP AMP INPUTS (Pins 13 and 14):** Pin 13 is the non-inverting and pin 14 the inverting inputs for the op amp section. In most multiplier applications, these terminals are connected to the multiplier outputs (pins 1 and 16). Note: When the op amp section is not used, these terminals should be grounded.

**OP AMP COMPENSATION (Pin 12):** The op amp section can be compensated for unconditional stability with a 20pF capacitor connected between pin 12 and pin 11. For op amp voltage gains greater than unity, this compensation capacitance can be reduced to improve slew rate and small signal bandwidth as shown in Figure 12.

**OP AMP OUTPUT (Pin 11):** This terminal serves as the output for the op amp section. It is internally protected against accidental short circuit conditions, and can sink or source 10mA of current into a resistive load. In most multiplier applications, pin 11 is the actual XR-2228 output, with the op amp inputs being connected to the multiplier outputs.

**APPLICATIONS INFORMATION**

**PART 1: ARITHMETIC OPERATIONS**

**Multiplication**

For most multiplication applications, the multiplier and op amp sections are interconnected as shown in Figure 14 to provide a single-ended analog output with a wide dynamic range. The circuit of Figure 14 provides a linear output swing of 10V for maximum input signals of 10V, with a scale factor $K = 0.1$. The trimming procedure for the circuit is as follows:

1. Apply 0V to both inputs and adjust the output offset to 0V using the output offset control.
2. Apply 20V p-p at 50Hz to the X-input and 0V to the Y-input. Trim the Y-offset adjust for minimum peak-to-peak output.
3. Apply 20V p-p to the Y-input and 0V to the X-input. Trim X-offset adjust for minimum peak-to-peak output.
4. Repeat step 1.
5. Apply +10V to both inputs and adjust scale factor for $V_o = +10V$. This step may be repeated with different amplitudes and polarities of input voltages to optimize accuracy over the entire range of input voltages, or over any specific portion of input voltage range.

**Figure 14. Multiplication Circuit**
PART II: ANALOG SIGNAL PROCESSING

Phase Detection

The multiplier section of the XR-2228 can be used as a linear phase-discriminator. A recommended circuit connection for this application is shown in Figure 16. In this case, the reference input (input 1) is applied to pin 2, and the input signal whose phase is to be detected (input 2) is applied to pin 5. For input signal amplitudes $\geq 50\text{mV}$ rms, the differential output voltage $V_o$ across pins 1 and 16 is directly proportional to the phase difference, $\phi$, between the two input signals. It can be expressed as

$$V_o(\phi) = 5 \left( \frac{2\phi}{\pi} - 1 \right)$$

where $\phi$ is the phase difference expressed in radians. Even though the op amp is, in this application, not used, it is necessary to bias its inputs within their common mode range. This is easily accomplished in the phase detector circuit of pin 16 by tying pins 13 and 14 to pin 3 (which puts pins 13 and 14 at half supply).

This latchup mode is nondestructive to the XR-2228, and is common to all analog division circuits. The divider circuit is trimmed as follows:

1. Apply $V_z = 0$ and trim the output offset adjustment for constant output voltage as $V_x$ is varied from $-1\text{V}$ to $-10\text{V}$.

2. Keeping $V_z = 0$, and applying $V_x = -10\text{V}$, trim the Y-offset adjust until $V_o = 0$.

3. Let $V_z = V_x$ and/or $V_z = -V_x$ and trim the X-offset adjustment for constant output voltage as $V_x$ is varied from $-1\text{V}$ to $-10\text{V}$.

4. If step 3 requires a large initial adjustment, repeat steps 1, 2 and 3.

5. Keeping $V_z = V_x$, adjust the scale factor trim for $V_o = -10\text{V}$ as $V_x$ is varied from $-1\text{V}$ to $-10\text{V}$.

The capacitors $C_1$ at pins 1 and 16 provide a low-pass filter with a time constant $T_1 = R_1 C_1$, where $R_1 = 5\text{k}\Omega$ is the international impedance level at these pins.

If needed, the phase conversion gain can be increased by using the op amp section of the XR-2228 to further amplify the output voltage, $V_o(\phi)$. The XR-2228 is suitable for phase detection of input frequencies up to 100MHz.
Synchronous AM Detection

Figure 17 is a typical circuit connection for synchronous AM detection for carrier frequencies up to 100MHz. The AM input signal is applied to the multiplier X- and Y-input terminals (pins 3 and 4) simultaneously.

The Y-gain terminals (pins 6 and 7) are shorted, and this section of the multiplier serves as a "limiter" for input signals $\geq 50$mVrms; the X-section of the multiplier operates in its linear mode. The low-pass filter capacitors, $C_1$, and at pins 1 and 16 are used to filter the carrier feedthrough. If desired, the op amp section can be used as an audio preamplifier to increase the demodulated output amplitude.

Triangle-to-Sinewave Conversion

A triangular input can be converted into a low distortion (THD < 1%) sinusoidal output with the XR-2228. A recommended connection for this application is shown in Figure 19. The triangle input signal is applied to the X-input (pin 2). The multiplier section rounds off the peaks of this input and converts it to a low distortion sine wave.

For the component values shown in Figure 19, the recommended input signal level at pin 2 is $\pm 300$mV pp, in order to obtain a 2V pp signal at pins 1 or 16, with $R_X$ set at approximately 100$\Omega$. The dc level at pin 5 can be used for adjusting the output amplitude, or providing amplitude modulation. The sensitivity of the output amplitude to the dc voltage level at pin 5 is inversely proportional to the external resistor across pins 6 and 7.

If higher amplitude output signal is required, the op amp section of XR-2228 can be used to provide additional amplification. If the op amp is not used, its inputs must be biased within common mode range to ensure proper device operation.

Phase-Locked AM Detection

The XR-2228 can be used in conjunction with any one of the commercially available monolithic phase-locked loop (PLL) IC's to provide phase-locked AM detection. In this manner, frequency-selective detection capabilities of PLL circuits can be extended to AM signals.

Precision Phase-Locked Loop Design

A precision phase-locked loop may be constructed using an XR-2209 voltage controlled oscillator and the XR-2228. (See Figure 18.) Due to the excellent temperature stability and wide sweep range of the XR-2209 this PLL circuit exhibits especially good stability of center frequency and wide lock range. In this application the XR-2228 serves as a phase comparator and level shifter. Resistor $R_L$ adjusts the loop gain of the PLL, thus varying the lock range. Tracking range may be varied from about 1.5:1 up to 12:1. For large values of $R_L$, temperature stability of center frequency is better than 30ppm/$^\circ$C.

The filter capacitor, $C_A$, connected across pins 1 and 16 of the multiplier outputs, serves as the post-detection low-pass filter. The value of $C_A$ is chosen to provide a compromise between the response time and the spurious noise rejection characteristics of the circuit: increasing $C_A$ improves the noise rejection characteristics of the circuit, but slows down the response time.

A detailed description of the principle of operation of the circuit of Figure 21 is given in Exar's Application Note AN-12 entitled: "Designing High Frequency Phase-Locked Loop Carrier-Detector Circuits".
