## Acknowledgments

First I want to thank my team partner and friend Colas Nahaboo who proposed me this project, and who actively participated to its design.

My thanks also go to my friend Lionel Mallet (Simulog) who heavily tested **XPM** by writing a dedicated icon editor called pixmap, and who often helped me making up my mind through long discussions when facing difficulties.

Finally I want to thank all the users who helped me to improve the library by giving feed back, sending bug reports with often patches to fix them, and even sometimes sending new chunks of code. It is also clear that the **XPM** library code would have never been so easy to compile on most of the today computers and operating systems without them.

## Support

You can mail any question or suggestion relative to **XPM** by electronic mail to [lehors@sophia.inria.fr](mailto:lehors@sophia.inria.fr). There is also a mailing list, please mail requests to [xpm-talk-request@sophia.inria.fr](mailto:xpm-talk-request@sophia.inria.fr) to subscribe. You can find the latest release by anonymous ftp on [avahi.inria.fr](http://avahi.inria.fr) (138.96.24.30) or [ftp.x.org](http://ftp.x.org) (198.112.44.100), and also an archive of the mailing list on [avahi](http://avahi.inria.fr).

# Chapter 1

## Introduction & History

First, Why another image format? We (Koala team at Bull Research, France) felt that most images bundled with X applications will be small "icons", and that since many applications are color-customizable, existing image formats such as gif, tiff, iff, etc... were intended for big images with well-defined colors and so weren't adapted to the task. So **XPM** was designed with these criterions in mind:

- be editable by hand (under emacs, vi...). Although this sounds pretty weird today.
- be includable in C code. It may be unreasonable to load 1000 pixmap files on each start of an application.
- be a portable, mailable ascii format.
- provide defaults for monochrome/color/grayscale renderings.
- provide overriding of colors. This way if the user wants your application to be bluish instead of greenish, you can use the SAME icon files.
- allow comments to be included in the file.
- compression must be managed apart of the format.

The original idea of this format comes from Daniel Dardailler and Colas Nahaboo who designed the first version in 1989. While Daniel wanted to take out from UIL<sup>1</sup> [Motif] the icon format, Colas thought it would be nice to do this in a way allowing to include the pixmap files in a C program just like XBM<sup>2</sup> files. Thus, Daniel developed and distributed in February 1989 the first version of the XPM library.

Then Daniel left for OSF<sup>3</sup> and I was hired by BULL. Colas told me about XPM and the need of a new version supporting symbolic colors to allow overriding of colors at load time, and different color defaults depending of the rendering the pixmap was displayed on. I liked the idea and worked on designing the new format with Colas and developed a new version of the library which I distributed in August 1990. In addition to the improvements mentioned above this new version of the format had the smart ability to support several programming language syntaxes. Indeed we thought it would be nice to let people include pixmap files in Lisp or any other language programs as well as in C programs. Actually that was really funny and quite satisfactory from a research point of view, but on the other hand, while people needed to have a standard format this has been claimed to be "n" different formats and not a single one. More over, it appeared that really few people where using syntaxes different from C. So we removed this multi-syntax feature from the format and settled the C syntax to come up with XPM version 3. This last version also supports hotspot coordinates, transparent color, and possible extensions.

Since August 1990, the XPM library has been released at various rhythms depending on the need and the time I could spent on it (this work having never been my main task), in order to always provide more features and to improve the code regarding both speed and robustness.

## Chapter 2

# The XPM Format

The **XPM** format presents a C syntax, in order to provide the ability to include **XPM** files in C and C++ programs. It is in fact an array of strings composed of six different sections as follows:

```
/* XPM */  
  
static char* <variable_name>[] = {  
    <Values>  
    <Colors>  
    <Pixels>  
    <Extensions>  
};
```

The words are separated by a white space which can be composed of space and tabulation characters.

The <Values> section is a string containing four or six integers in base 10 that correspond to: the pixmap width and height, the number of colors, the number of characters per pixel (so there is no limit on the number of colors), and, optionally the hotspot coordinates and the **XPMEXT** tag if there is any extension following the <Pixels> section.

```
<width> <height> <ncolors> <cpp> [<x_hotspot> <y_hotspot>] [XPMEXT]
```

The Colors section contains as many strings as there are colors, and each string is as follows:

```
<chars> {<key> <color>}+
```

Where <chars> is the <chars\_per\_pixel> length string (not surrounded by anything) representing the pixels, <color> is the specified color, and <key> is a keyword describing in which context this color should be used. Currently the keys may have the following values:

m	for mono visual
s	for symbolic name
g4	for 4-level grayscale
g	for grayscale with more than 4 levels
c	for color visual

Colors can be specified by giving the colordname, a # followed by the RGB code in hexadecimal, or a % followed by the HSV code (not implemented). The symbolic name provides the ability of specifying the colors at load time and not to hard-code them in the file.

Also the string **None** can be given as a colordname to mean “transparent”. Transparency is supported by the **XPM** library by providing a masking bitmap in addition to the pixmap. This mask can then be used either as a clip-mask of

an Xlib GC, or a shape-mask of a window using the X11 Nonrectangular Window Shape Extension [XShape].

The `<Pixels>` section is composed by `<height>` strings of `<width> * <chars_per_pixel>` characters, where every `<chars_per_pixel>` length string must be one of the previously defined groups in the `<Colors>` section.

Then follows the `<Extensions>` section which must be labeled, if not empty, in the `<Values>` section as previously described. This section may be composed by several `<Extension>` subsections which may be of two types:

- one stand alone string composed as follows:

```
XPTEXT <extension-name> <extension-data>
```

- or a block composed by several strings:

```
XPTEXT <extension-name>
```

```
<related extension-data composed of several strings>
```

Finally, if not empty, this section must end by the following string:

```
XPTEXT
```

To avoid possible conflicts with extension names in shared files, they should be prefixed by the name of the company. This would ensure uniqueness.

Below is an example which is the XPM file of a plaid pixmap. This is a 22x22 pixmap, with 4 colors and 2 characters per pixel. The hotspot coordinates are (0, 0). There are symbols and default colors for color and monochrome visuals. Finally there are two extensions.

```

/* XPM */
static char *plaid[] = {
/* plaid pixmap
 * width height ncolors chars_per_pixel */
"22 22 4 2 0 0 XPMEXT",
/* colors */
"  c red      m white  s light_color ",
"Y  c green   m black  s lines_in_mix ",
"+  c yellow  m white  s lines_in_dark ",
"x                m black s dark_color ",
/* pixels */
"x  x  x x x  x  x x x x x x + x x x x x ",
"  x  x  x  x  x  x x x x x x x x x x x ",
"x  x  x x x  x  x x x x x x + x x x x x ",
"  x  x  x  x  x  x x x x x x x x x x x ",
"x  x  x x x  x  x x x x x x + x x x x x ",
"Y Y Y Y Y x Y Y Y Y Y + x + x + x + x + ",
"x  x  x x x  x  x x x x x x + x x x x x ",
"  x  x  x  x  x  x x x x x x x x x x x ",
"x  x  x x x  x  x x x x x x + x x x x x ",
"  x  x  x  x  x  x x x x x x x x x x x ",
"x  x  x x x  x  x x x x x x + x x x x x ",
"                x      x  x  x Y x  x  x ",
"                x      x  x  Y  x  x  x ",
"                x      x  x  x Y x  x  x ",
"                x      x  x  Y  x  x  x ",
"                x      x  x  Y  x  x  x ",
"                x      x  x  x Y x  x  x ",
"x x x x x x x x x x x x x x x x x x x x x ",
"                x      x  x  x Y x  x  x ",
"                x      x  x  Y  x  x  x ",
"                x      x  x  x Y x  x  x ",
"                x      x  x  Y  x  x  x ",
"                x      x  x  x Y x  x  x "
"XPMEXT ext1 data1",
"XPMEXT ext2",
"data2_1",
"data2_2",
"XPMENDEXT"
};

```

## Chapter 3

# The XPM Library

The **XPM** library basically provides two sets of Xlib-level functions in the C language. Most people should only know about the first one since it provides what most likely one need with a simple interface. The second set, which stands as a lower level called from the first one, is designed to be used from within applications which have more specific needs such as a pixmap editor or applications which needs to cache data such as **XPM** files.

### 3.1 The Basic Level Interface

The basic level interface allows to deal with XImage, Pixmap, **XPM** file, data (included **XPM** file), buffer (**XPM** file in memory), and in many ways.

The following subsections describe these functions and how to use them.

#### 3.1.1 The structures

To provide a simple interface all the functions take, in addition to their main arguments such as a filename, a structure called **XpmAttributes**. This structure is composed of attributes to pass data such as colormap, visual, and attributes to retrieve returned data such as pixmap's width and height. The **XpmAttributes** structure is defined as follows:

```
typedef struct {
    unsigned long valuemask;           /* Specifies which attributes are defined */
    Visual *visual;                   /* Specifies the visual to use */
    Colormap colormap;                /* Specifies the colormap to use */
    unsigned int depth;               /* Specifies the depth */
    unsigned int width;               /* Returns the width of the created pixmap */
    unsigned int height;              /* Returns the height of the created pixmap */
    unsigned int x_hotspot;           /* Returns the x hotspot's coordinate */
    unsigned int y_hotspot;           /* Returns the y hotspot's coordinate */
    unsigned int cpp;                 /* Specifies the number of char per pixel */
    Pixel *pixels;                    /* List of used color pixels */
    unsigned int npixels;              /* Number of pixels */
    XpmColorSymbol *colorsymbols;     /* Array of color symbols to override */
    unsigned int numsymbols;          /* Number of symbols */
    char *rgb_fname;                  /* RGB text file name */
    unsigned int nextensions;         /* Number of extensions */
    XpmExtension *extensions;         /* Array of extensions */
    int ncolors;                      /* Number of colors */
    XpmColor *colorTable;             /* Color table pointer */
}
```

```

        char *hints_cmt;           /* Comment of the hints section */
        char *colors_cmt;         /* Comment of the colors section */
        char *pixels_cmt;        /* Comment of the pixels section */
        unsigned int mask_pixel;  /* Transparent pixel's color table index */
/* Color Allocation Directives */
        unsigned int exactColors; /* Only use exact colors for visual */
        unsigned int closeness;   /* Allowable RGB deviation */
        unsigned int red_closeness; /* Allowable red deviation */
        unsigned int green_closeness; /* Allowable green deviation */
        unsigned int blue_closeness; /* Allowable blue deviation */
        int color_key;            /* Use colors from this color set */
} XpmAttributes;

```

The valuemask is the bitwise inclusive OR of the valid attribute mask bits. If the valuemask is zero, the attributes are ignored and not referenced and default values are taken for needed attributes which are not specified. This valuemask had to be part of the structure to let **XPM** functions modify its value when returning possible data such as hotspot coordinates or when requested data cannot be returned. In fact, the **XPM** library functions will automatically return as many data as possible as long as this doesn't lead to some memory allocation. Otherwise data are returned only on request.

To set an attribute, set the appropriate member of the **XpmAttributes** structure and OR in the corresponding value bitmask in the valuemask member. The symbols for the value mask bits and **XpmAttributes** structure are:

Symbol Name	Symbol Value	Related Members	Comments
<b>XpmVisual</b>	(1L<<0)	visual	Default value is: DefaultVisual(display, DefaultScreen(display)).
<b>XpmColormap</b>	(1L<<1)	colormap	Default value is: DefaultColormap(display, DefaultScreen(display)).
<b>XpmDepth</b>	(1L<<2)	depth	Default value is: DefaultDepth(display, DefaultScreen(display)).
<b>XpmSize</b>	(1L<<3)	width, height	Will be set when creating an XImage or a Pixmap.
<b>XpmHotspot</b>	(1L<<4)	x_hotspot, y_hotspot	Will be set if hotspot coordinates are found when parsing.
<b>XpmCharsPerPixel</b>	(1L<<5)	cpx	
<b>XpmColorSymbols</b>	(1L<<6)	colorsymbols, numcolorsymbols	
<b>XpmRgbFilename</b>	(1L<<7)	rgb_fname	

Symbol Name	Symbol Value	Related Members	Comments
<b>XpmInfos</b>	(1L<<8)	cpp, pixels, npixels, colorTable, ncolors, hints_cmt, colors_cmt, pixels_cmt, mask_pixel	Obsolete. colorTable cast to (XpmColor **).
<b>XpmReturnInfos</b>	<i>idem</i>	<i>idem</i>	Obsolete. Will be unset in case of memory allocation failure.
<b>XpmPixels</b>	(1L<<9)	pixels, npixels	npixels will differ from ncolors if several colors are bound to the same pixel, and if there is a mask (None color).
<b>XpmReturnPixels</b>	<i>idem</i>	<i>idem</i>	Will be unset in case of memory allocation failure.
<b>XpmExtensions</b>	(1L<<10)	extensions, nextensions	
<b>XpmReturnExtensions</b>	<i>idem</i>	<i>idem</i>	Will be unset in case of memory allocation failure.
<b>XpmExactColors</b>	(1L<<11)	exactColors	Possible values are: False (0) or True (1).
<b>XpmCloseness</b>	(1L<<12)	closeness	Possible values are integers within the range: 0 to 65535.
<b>XpmRGBCloseness</b>	(1L<<13)	red_closeness, green_closeness, blue_closeness	Possible values are integers within the range: 0 to 65535.
<b>XpmColorKey</b>	(1L<<14)	color_key	Possible values are: XPM_MONO, XPM_GRAY4, XPM_GRAY, XPM_COLOR.
<b>XpmColorTable</b>	(1L<<15)	colorTable, ncolors	
<b>XpmReturnColorTable</b>	<i>idem</i>	<i>idem</i>	Will be unset in case of memory allocation failure.

**NOTE:** In any case the **XpmAttributes** valuemask must be set to some valid value, at least zero, otherwise unpredictable errors can occur.

The **colorTable** field of the **XpmAttributes** structure is an array of **XpmColor** (page 24) which is compatible with an **XpmImage** colortable (page 24) and should be used with the corresponding flags: **XpmColorTable** and **XpmReturnColorTable**. But in order to be backward compatible this field is cast to (**XpmColor \*\***), which is equivalent to (char \*\*\*), when it is used with the old flags: **XpmInfos** and **XpmReturnInfos**. In this case the colorTable is a two dimensional array of strings, organized as follows:

colorTable[color#][0] points to the character string associated to the color.

colorTable[color#][1] points to the symbolic name of the color.  
colorTable[color#][2] points to the default color for monochrome visuals.  
colorTable[color#][3] points to the default color for 4-level grayscale visuals.  
colorTable[color#][4] points to the default color for other grayscale visuals.  
colorTable[color#][5] points to the default color for color visuals.

Note that this can also be seen as an array of pointers to **XpmColor** structures which is then organized as follows:

colorTable[#color] points to the **XpmColor** structure retaining related data.

Comments are limited to a single comment string by section. If more exist in the read file, then only the last comment of each section will be stored.

To get information back while writing out to a file, you can just set the mask bits **XpmReturnInfos** to the valuemask of an **XpmAttributes** structure that you pass to the **XpmReadFileToPixmap** (page 16) function while reading the file, and then give the structure back to the **XpmWriteFileFromPixmap** (page 17) function while writing. However this method should be considered as obsolete since the advanced level interface provides a cleaner way to do so.

To allow overriding of colors at load time the **XPM** library defines the **XpmColorSymbol** structure which contains:

```
typedef struct {  
    char *name;           /* Symbolic color name */  
    char *value;          /* Color value */  
    Pixel pixel;          /* Color pixel */  
} XpmColorSymbol;
```

So, to override default colors at load time, you just have to pass, via the **XpmAttributes** structure, a list of **XpmColorSymbol** elements containing the desired colors to the **XpmReadFileToPixmap** or **XpmCreatePixmapFromData** (page 18) functions. These colors can be specified by giving the color name in the value member or directly by giving the corresponding pixel in the pixel member. In the latter case the value member must be set to **NULL** otherwise the given pixel will not be considered.

In addition, it is possible to set the pixel for a specific color **value** at load time by setting the color name to **NULL**, and setting the value and pixel fields appropriately. For example, by setting the color name to **NULL**, the value to “red” and the pixel to 51, all symbolic colors that are assigned to “red” will be set to pixel 51. It is even possible to specify the pixel used for the transparent color “none” when no mask is required.

To pass and retrieve extension data use the **XpmExtension** structure which is defined below:

```
typedef struct {  
    char *name;           /* name of the extension */  
    unsigned int nlines;  /* number of lines in this extension */  
    char **lines;         /* pointer to the extension array of strings */  
} XpmExtension;
```

To retrieve possible extension data stored in an **XPM** file or data, you must set the mask bits **XpmReturnExtensions** to the valuemask of an **XpmAttributes** structure that you pass to the read function you use. Then the same structure may be passed the same way to any write function if you set the mask bits **XpmExtensions** to the valuemask.

### 3.1.2 Functions to deal with XPM files

To create an **XImage** from an **XPM** file, use **XpmReadFileToImage**.

```
int XpmReadFileToImage(display, filename, image_return, shapeimage_return, attributes)
```

```
    Display *display;
    char *filename;
    XImage **image_return;
    XImage **shapeimage_return;
    XpmAttributes *attributes;
```

<i>display</i>	Specifies the connection to the X server.
<i>filename</i>	Specifies the file name to use.
<i>image_return</i>	Returns the image which is created.
<i>shapeimage_return</i>	Returns the shape mask image which is created if the color None is used.
<i>attributes</i>	Specifies the location of a structure to get and store information (or NULL).

The **XpmReadFileToImage** function reads in a file in the **XPM** format. If the file cannot be opened it returns **XpmOpenFailed**. If the file can be opened but does not contain valid **XPM** data, it returns **XpmFileInvalid**. If insufficient working storage is allocated, it returns **XpmNoMemory**.

If the passed **XpmAttributes** structure pointer is not **NULL**, **XpmReadFileToImage** looks for the following attributes: **XpmVisual**, **XpmColormap**, **XpmDepth**, **XpmColorSymbols**, **XpmExactColors**, **XpmCloseness**, **XpmRGBCloseness**, **XpmReturnPixels**, **XpmReturnExtensions**, sets the **XpmSize**, the **XpmCharsPerPixel**, and possibly the **XpmHotspot** attributes when returning. As a backward compatibility feature, **XpmReadFileToImage** also looks for the **XpmReturnInfos** attributes. In any case, if requested data cannot be returned because of insufficient memory storage, **XpmReadFileToImage** will change the valuemask to mention this and will try to continue. So the caller should check on this before accessing this data.

Note: The valuemask of the passed **XpmAttributes** must be set to some valid value, at least zero, otherwise unpredictable errors can occur.

**XpmReadFileToImage** allocates colors, as read from the file or possibly overridden as specified in the **XpmColorSymbols** attributes. The colors are allocated using the color settings for the visual specified by the **XpmColorKey** attribute, which has the value **XPM\_MONO**, **XPM\_GRAY4**, **XPM\_GRAY**, or **XPM\_COLOR**. If the **XpmColorKey** attribute is not set it is determined by examining the type of visual.

If no default value exists for the specified visual, it first looks for other defaults nearer to the monochrome visual type and secondly nearer to the color visual type. If the color which is found is not valid (cannot be parsed), it looks for another default one according to the same algorithm.

If allocating a color fails, and the **closeness** attribute is set, it tries to find a color already in the colormap that is closest to the desired color, and uses that. If no color can be found that is within **closeness** of the Red, Green and Blue components of the desired color, it reverts to trying other default values as explained above. For finer control over the closeness requirements of a particular icon, the **red\_closeness**, **green\_closeness**, and **blue\_closeness** attributes may be used instead of the more general **closeness** attribute.

The RGB components are integers within the range 0 (black) to 65535 (white). A closeness of less than 10000, for example, will cause only quite close colors to be matched, while a closeness of more than 50000 will allow quite dis-

similar colors to match. Specifying a closeness of more than 65535 will allow any color to match, thus forcing the icon to be drawn in color no matter how bad the colormap is. The value 40000 seems to be about right for many situations requiring reasonable but not perfect matches. With this setting the color must only be within the same general area of the RGB cube as the desired color.

If the **exactColors** attribute is set it then returns **XpmColorError**, otherwise it creates the images and returns **XpmSuccess**. If no color is found, and no close color exists or is wanted, and all visuals have been exhausted, **XpmColorFailed** is returned.

**XpmReadFileToImage** returns the created image to `image_return` if not **NULL** and possibly the created shapemask to `shapemask_return` if not **NULL** and the color **None** is used. If required it stores into the **XpmAttributes** structure the list of the used pixels.

When finished the caller must free the images using **XDestroyImage**, the colors using **XFreeColors**, and possibly the data returned into the **XpmAttributes** using **XpmFreeAttributes** (page 23).

In addition, on systems which support such features **XpmReadFileToImage** deals with compressed files by forking an **uncompress** or **gzip** process and reading from the piped result. It assumes that the specified file is compressed if the given file name ends by `'.Z'` or `'.gz'`. In case the file name does not end so, **XpmReadFileToImage** first looks for a file of which the name is the given one followed by `'.Z'` or `'.gz'`; then if such a file does not exist, it looks for the given file (assumed as not compressed). And if instead of a file name **NULL** is passed to **XpmReadFileToImage**, it reads from the standard input.

To create a **Pixmap** from an **XPM** file, use **XpmReadFileToPixmap**.

```
int XpmReadFileToPixmap(display, d, filename, pixmap_return, shapemask_return, attributes)
```

```
    Display *display;
    Drawable d;
    char *filename;
    Pixmap *pixmap_return;
    Pixmap *shapemask_return;
    XpmAttributes *attributes;
```

<i>display</i>	Specifies the connection to the X server.
<i>d</i>	Specifies which screen the pixmap is created on.
<i>filename</i>	Specifies the file name to use.
<i>pixmap_return</i>	Returns the pixmap which is created.
<i>shapemask_return</i>	Returns the shapemask which is created if the color <b>None</b> is used.
<i>attributes</i>	Specifies the location of a structure to get and store information (or <b>NULL</b> ).

The **XpmReadFileToPixmap** function creates X images using **XpmReadFileToImage** (page 15) and thus returns the same errors. In addition on success it then creates the related pixmaps, using **XPutImage**, which are returned to `pixmap_return` and `shapemask_return` if not **NULL**, and finally destroys the created images using **XDestroyImage**.

When finished the caller must free the pixmaps using **XFreePixmap**, the colors using **XFreeColors**, and possibly the data returned into the **XpmAttributes** using **XpmFreeAttributes**.

**XpmWriteFileFromImage** writes out an **XImage** to an **XPM** file.

```
int XpmWriteFileFromImage(display, filename, image, shapeimage, attributes)
```

```
    Display *display;  
    char *filename;  
    XImage *image;  
    XImage *shapeimage;  
    XpmAttributes *attributes;
```

<i>display</i>	Specifies the connection to the X server.
<i>filename</i>	Specifies the file name to use.
<i>image</i>	Specifies the image.
<i>shapeimage</i>	Specifies the shape mask image.
<i>attributes</i>	Specifies the location of a structure containing information (or NULL).

The **XpmWriteFileFromImage** function writes an image and its possible shapeimage out to a file in the **XPM** format. If the file cannot be opened, it returns **XpmOpenFailed**. If insufficient working storage is allocated, it returns **XpmNoMemory**. If no error occurs then it returns **XpmSuccess**.

If the passed **XpmAttributes** structure pointer is not **NULL**, **XpmWriteFileFromImage** looks for the following attributes: **XpmColormap**, **XpmHotspot**, **XpmCharsPerPixel**, **XpmRgbFilename**, and **XpmExtensions**. As a backward compatibility feature, **XpmWriteFileFromImage** also looks for the **XpmInfos** attributes.

If the filename contains an extension such as “.xpm”, in order to get a valid C variable name, the dot character is replaced by an underscore ‘\_’ when writing out. As a backward compatibility feature, if the **XpmInfos** attributes are defined it writes out possible stored information such as comments, color defaults and symbol. Finally, if the **XpmRgbFilename** attribute is defined, **XpmWriteFileFromImage** searches for color names in this file and if found writes them out instead of the rgb values.

In addition on systems which support such features if the given file name ends by ‘.Z’ or ‘.gz’ it is assumed to be a compressed file. Then, **XpmWriteFileFromImage** writes to a piped **compress** or **gzip** process. And if instead of a file name **NULL** is passed to **XpmWriteFileFromImage**, it writes to the standard output.

To write out a **Pixmap** to an **XPM** file, use **XpmWriteFileFromPixmap**.

```
int XpmWriteFileFromPixmap(display, filename, pixmap, shapemask, attributes)
```

```
    Display *display;  
    char *filename;  
    Pixmap pixmap;  
    Pixmap shapemask;  
    XpmAttributes *attributes;
```

<i>display</i>	Specifies the connection to the X server.
<i>filename</i>	Specifies the file name to use.
<i>pixmap</i>	Specifies the pixmap.
<i>shapemask</i>	Specifies the shape mask pixmap.
<i>attributes</i>	Specifies the location of a structure containing information (or NULL).

If the passed **XpmAttributes** structure pointer is not **NULL**, **XpmWriteFileFromPixmap** looks for the following attributes: **XpmSize**. If they are not defined it performs an **XGetGeometry** operation. Then it uses **XGetImage** to get from the given pixmaps the related X images which are passed to **XpmWriteFileFromImage**. Finally **XpmWriteFileFromPixmap** destroys the created images using **XDestroyImage**. The **XpmWriteFileFromPixmap** function returns the same errors as **XpmWriteFileFromImage**.

### 3.1.3 Functions to deal with XPM data

An **XPM** data is an array of character strings which may be obtained by simply including an **XPM** file into a C program.

To create an **XImage** from an **XPM** data, use **XpmCreateImageFromData**.

```
int XpmCreateImageFromData(display, data, image_return, shapeimage_return, attributes)
    Display *display;
    char **data;
    XImage **image_return;
    XImage **shapeimage_return;
    XpmAttributes *attributes;
```

<i>display</i>	Specifies the connection to the X server.
<i>data</i>	Specifies the location of the data.
<i>image_return</i>	Returns the image which is created.
<i>shapeimage_return</i>	Returns the shape mask image which is created if the color None is used.
<i>attributes</i>	Specifies the location of a structure to get and store information (or <b>NULL</b> ).

The **XpmCreateImageFromData** function allows you to include in your C program an **XPM** file which was written out by functions such as **XpmWriteFileFromImage** or **XpmWriteFileFromPixmap** without reading in the file.

**XpmCreateImageFromData** exactly works as **XpmReadFileToImage** (page 15) does and returns the same way. It just reads data instead of a file. Here again, it is the caller's responsibility to free the returned images, the colors and possibly the data returned into the **XpmAttributes** structure.

To create a **Pixmap** from an **XPM** data, use **XpmCreatePixmapFromData**.

```
int XpmCreatePixmapFromData(display, d, data, pixmap_return, shapemask_return, attributes)
    Display *display;
    Drawable d;
    char **data;
    Pixmap *pixmap_return;
    Pixmap *shapemask_return;
    XpmAttributes *attributes;
```

<i>display</i>	Specifies the connection to the X server.
<i>d</i>	Specifies which screen the pixmap is created on.
<i>data</i>	Specifies the location of the data.

<i>pixmap_return</i>	Returns the pixmap which is created.
<i>shapemask_return</i>	Returns the shape mask pixmap which is created if the color None is used.
<i>attributes</i>	Specifies the location of a structure to get and store information (or NULL).

The **XpmCreatePixmapFromData** function creates X images using **XpmCreateImageFromData** (page 18) and thus returns the same errors. In addition on success it then creates the related pixmaps, using **XPutImage**, which are returned to *pixmap\_return* and *shapemask\_return* if not **NULL**, and finally destroys the created images using **XDestroyImage**.

Do not forget to free the returned pixmaps, the colors, and possibly the data returned into the **XpmAttributes** structure when done.

In some cases, one may want to create an **XPM** data from an **XImage**, to do so use **XpmCreateDataFromImage**.

```
int XpmCreateDataFromImage(display, data_return, image, shapeimage, attributes)
```

```
    Display *display;  
    char ***data_return;  
    XImage *image;  
    XImage *shapeimage;  
    XpmAttributes *attributes;
```

<i>display</i>	Specifies the connection to the X server.
<i>data_return</i>	Returns the data which is created.
<i>image</i>	Specifies the image.
<i>shapeimage</i>	Specifies the shape mask image.
<i>attributes</i>	Specifies the location of a structure containing information (or NULL).

The **XpmCreateDataFromImage** function exactly works as **XpmWriteFileFromImage** (page 17) does and returns the same way. It just writes to a single block malloc'ed data instead of to a file. It is the caller's responsibility to free the data, using **XpmFree** when finished.

**XpmCreateDataFromPixmap** creates an **XPM** data from a **Pixmap**.

```
int XpmCreateDataFromPixmap(display, data_return, pixmap, shapemask, attributes)
```

```
    Display *display;  
    char ***data_return;  
    Pixmap pixmap;  
    Pixmap shapemask;  
    XpmAttributes *attributes;
```

<i>display</i>	Specifies the connection to the X server.
<i>data_return</i>	Returns the data which is created.
<i>pixmap</i>	Specifies the pixmap.
<i>shapemask</i>	Specifies the shape mask pixmap.
<i>attributes</i>	Specifies the location of a structure containing information (or NULL).

The **XpmCreateDataFromPixmap** function uses **XGetImage** to get from the given pixmaps the related X images

which are passed to **XpmCreateDataFromImage**. Then it destroys the created images using **XDestroyImage**. **XpmCreateDataFromPixmap** returns the same errors as **XpmCreateDataFromImage**.

### 3.1.4 Functions to deal with XPM files and data

To directly transform an **XPM** file to and from an **XPM** data array, without requiring an open X display, use **XpmReadFileToData** and **XpmWriteFileFromData**.

**XpmReadFileToData** allocates and fills an **XPM** data array from an **XPM** file.

```
int XpmReadFileToData(filename, data_return)
    char *filename;
    char ***data_return;

filename          Specifies the file name to read.
data_return       Returns the data array created.
```

**XpmReadFileToData** returns **XpmOpenFailed** if it cannot open the file, **XpmNoMemory** if insufficient working storage is allocated, **XpmFileInvalid** if this is not a valid **XPM** file, and **XpmSuccess** otherwise. The allocated data returned by **XpmReadFileToData** should be freed with **XpmFree** when done.

**XpmWriteFileFromData** writes an **XPM** data array to an **XPM** file.

```
int XpmWriteFileFromData(filename, data)
    char *filename;
    char **data;

filename          Specifies the file name to write.
data              Specifies the data array to read.
```

**XpmReadFileToData** returns **XpmOpenFailed** if it cannot open the file, **XpmFileInvalid** if this is not a valid **XPM** data, and **XpmSuccess** otherwise.

### 3.1.5 Functions to deal with XPM buffers

An **XPM** buffer is a character string which may be obtained by simply making the exact copy of an **XPM** file into memory.

To create an **XImage** from an **XPM** buffer, use **XpmCreateImageFromBuffer**.

```
int XpmCreateImageFromBuffer(display, buffer, image_return, shapeimage_return, attributes)
    Display *display;
    char *buffer;
    XImage **image_return;
    XImage **shapeimage_return;
    XpmAttributes *attributes;
```

<i>display</i>	Specifies the connection to the X server.
<i>buffer</i>	Specifies the location of the buffer.
<i>image_return</i>	Returns the image which is created.
<i>shapeimage_return</i>	Returns the shape mask image which is created if the color None is used.
<i>attributes</i>	Specifies the location of a structure to get and store information (or NULL).

The **XpmCreateImageFromBuffer** works the same way as **XpmReadFileToImage** (page 15), it just parses the buffer instead of the file. Be aware that the feature provided on some systems by **XpmReadFileToImage** to deal with compressed files is not available here.

To create a **Pixmap** from an **XPM** buffer, use **XpmCreatePixmapFromBuffer**.

```
int XpmCreatePixmapFromBuffer(display, d, buffer, pixmap_return, shapemask_return, attributes)
```

```
    Display *display;  
    Drawable d;  
    char *buffer;  
    Pixmap *pixmap_return;  
    Pixmap *shapemask_return;  
    XpmAttributes *attributes;
```

<i>display</i>	Specifies the connection to the X server.
<i>d</i>	Specifies which screen the pixmap is created on.
<i>buffer</i>	Specifies the location of the buffer.
<i>pixmap_return</i>	Returns the pixmap which is created if the color None.
<i>shapemask_return</i>	Returns the shape mask pixmap which is created if the color None is used.
<i>attributes</i>	Specifies the location of a structure to get and store information.

The **XpmCreatePixmapFromBuffer** function works the same way as **XpmReadFileToPixmap** (page 16), it just calls **XpmCreateImageFromBuffer** instead of **XpmReadFileToImage**.

To create an **XPM** buffer from an **XImage**, use **XpmCreateBufferFromImage**.

```
int XpmCreateBufferFromImage(display, buffer_return, image, shapeimage, attributes)
```

```
    Display *display;  
    char **buffer_return;  
    XImage *image;  
    XImage *shapeimage;  
    XpmAttributes *attributes;
```

<i>display</i>	Specifies the connection to the X server.
<i>buffer_return</i>	Returns the buffer which is created.
<i>image</i>	Specifies the image.
<i>shapeimage</i>	Specifies the shape mask image.
<i>attributes</i>	Specifies the location of a structure containing information (or NULL).

The **XpmCreateBufferFromImage** works as **XpmWriteFileFromImage** (page 17), it just writes to a malloc'ed

buffer instead of to a file. The caller should free the buffer using **XpmFree** when finished.

**XpmCreateBufferFromPixmap** creates an **XPM** buffer from a **Pixmap**.

```
int XpmCreateBufferFromPixmap(display, buffer_return, pixmap, shapemask, attributes)
    Display *display;
    char **buffer_return;
    Pixmap pixmap;
    Pixmap shapemask;
    XpmAttributes *attributes;
```

<i>display</i>	Specifies the connection to the X server.
<i>buffer_return</i>	Returns the buffer which is created.
<i>pixmap</i>	Specifies the pixmap.
<i>shapemask</i>	Specifies the shape mask pixmap.
<i>attributes</i>	Specifies the location of a structure containing information (or NULL).

The **XpmCreateBufferFromPixmap** function works as **XpmWriteFileFromPixmap** (page 17), it just calls **XpmCreateBufferFromImage** instead of **XpmWriteFileFromImage**. Once again, the caller should free the buffer using **XpmFree** when finished.

### 3.1.6 Functions to deal with XPM files and buffers

As a convenience, the **XpmReadFileToBuffer** and **XpmWriteFileFromBuffer** are provided to copy a file to a buffer and to write a file from a buffer. Thus for instance one may decide to use **XpmReadFileToBuffer**, **XpmCreatePixmapFromBuffer**, and **XpmFree** instead of **XpmReadFileToPixmap**. On some systems this may lead to a performance improvement, since the parsing will be performed in memory, but it uses more memory.

**XpmReadFileToBuffer** allocates and fills a buffer from a file.

```
int XpmReadFileToBuffer(filename, buffer_return)
    char *filename;
    char **buffer_return;
```

<i>filename</i>	Specifies the file name to read.
<i>buffer_return</i>	Returns the buffer created.

**XpmReadFileToBuffer** returns **XpmOpenFailed** if it cannot open the file, returns **XpmNoMemory** if insufficient working storage is allocated, and **XpmSuccess** otherwise. The allocated buffer returned by **XpmReadFileToBuffer** should be freed with **XpmFree** when done.

**XpmWriteFileFromBuffer** writes a buffer to a file.

```
int XpmWriteFileFromBuffer(filename, data)
    char *filename;
    char *buffer;
```

*filename*                      Specifies the file name to write.  
*buffer*                        Specifies the buffer to read.

**XpmWriteFileFromBuffer** returns **XpmOpenFailed** if it cannot open the file, and **XpmSuccess** otherwise.

### 3.1.7 Miscellaneous functions

To free possible data stored into an **XpmAttributes** structure use **XpmFreeAttributes**.

```
int XpmFreeAttributes(attributes)
    XpmAttributes *attributes;
```

*attributes* Specifies the structure to free.

The **XpmFreeAttributes** frees the structure members which have been malloc'ed such as the pixels list.

To dynamically allocate an **XpmAttributes** structure use the **XpmAttributesSize** function.

```
int XpmAttributesSize()
```

The **XpmAttributesSize** function provides application using dynamic libraries with a safe way to allocate and then refer to an **XpmAttributes** structure, disregarding whether the **XpmAttributes** structure size has changed or not since compiled.

To free data possibly stored into an array of **XpmExtension** use **XpmFreeExtensions**.

```
int XpmFreeExtensions(extensions, nextensions)
    XpmExtension *extensions;
```

*extensions*                      Specifies the array to free.  
*nextensions*                    Specifies the number of extensions.

This function frees all data stored in every extension and the array itself. Note that **XpmFreeAttributes** call this function and thus most of the time it should not need to be explicitly called.

To free any data allocated by an **XPM** function use the **XpmFree** function.

```
int XpmFree(ptr)
    char *ptr;
```

*ptr* Specifies the data to free.

The current distribution of the **XPM** library uses the standard memory allocation functions and thus **XpmFree** is nothing else than a define to the standard **free**. However since these functions may be redefined in specific environments it is wise to use **XpmFree**.

To get data when building an error message, one can use **XpmGetErrorString**

```
char *XpmGetErrorString(errorcode)
    int errorcode;
```

*errorcode* Specifies the **XPM** error.

`XpmGetErrorString` returns a string related to the given **XPM** error code.

The **XpmLibraryVersion** can be used when one needs to figure out which version of the library is in use.

```
int XpmLibraryVersion()
```

The value returned by **XpmLibraryVersion** can be compared to the value of **XpmIncludeVersion** which is defined in the header file "xpm.h". These numbers are computed with the following formula:

$(XpmFormat * 100 + XpmVersion) * 100 + XpmRevision$

Where `XpmFormat` is the version number of the format, `XpmVersion` is the library version number (which changes only if the API changes), and `XpmRevision` is the library minor version number.

## 3.2 The Advanced Level Interface

The advanced level interface is a set of functions that applications, such as icon editors, which needs to retrieve all the information stored in an **XPM** file and applications which perform data caching can use.

The following subsections describe these functions and how to use them.

### 3.2.1 The structures

The purpose of the structures defined in this section is to be able to store **XPM** images in memory to avoid any additional parsing without losing information such as color defaults, symbolic color names, and comments.

Indeed, considering the **XPM** format one can see that there is a lot more information related to a color than just an rgb value or a colormap index, the **XpmColor** structure allows to store the different color defaults, the symbolic name of a color, and the characters string which represents it.

```
typedef struct {
    char *string;           /* characters string */
    char *symbolic;        /* symbolic name */
    char *m_color;         /* monochrome default */
    char *g4_color;        /* 4 level grayscale default */
    char *g_color;         /* other level grayscale default */
    char *c_color;         /* color default */
} XpmColor;
```

The **XpmImage** structure is defined to store the image data definition with its size, the length of the characters strings representing each color, and the related color table.

```
typedef struct {
    unsigned int width;    /* image width */
```

```

        unsigned int height;           /* image height */
        unsigned int cpp;              /* number of characters per pixel */
        unsigned int ncolors;          /* number of colors */
        XpmColor *colorTable;          /* list of related colors */
        unsigned int *data;            /* image data */
    } XpmImage

```

The **XpmImage** data is an array of width\*height color indexes, each color index referencing the related color in the colortable.

In addition, to store all the possible optional data which an **XPM** file may contain, an **XpmInfo** structure can be passed to the reading function. This structure can then be given back to the writing function. Comments are limited to a single strings by **XPM** format section. If more exist in the read file, then only the last comment of each section will be stored.

```

typedef struct {
    unsigned long valuemask;           /* Specifies which attributes are defined */
    char *hints_cmt;                  /* comment of the hints section */
    char *colors_cmt;                 /* comment of the colors section */
    char *pixels_cmt;                 /* comment of the pixels section */
    unsigned int x_hotspot;            /* Returns the x hotspot's coordinate */
    unsigned int y_hotspot;            /* Returns the y hotspot's coordinate */
    unsigned int nextensions;          /* number of extensions */
    XpmExtension *extensions;          /* pointer to array of extensions */
} XpmInfo;

```

The valuemask is the bitwise inclusive OR of the valid attribute mask bits. If the valuemask is zero, the attributes are ignored and not referenced. This valuemask had to be part of the structure to let **XPM** functions modify its value when returning possible data such as hotspot coordinates or when requested data cannot be returned. In fact, the **XPM** library functions will automatically return the hotspot coordinates since this doesn't lead to any memory allocation. On the other hand, comments and extensions are returned only on request.

To set an attribute, set the appropriate member of the **XpmInfo** structure and OR in the corresponding value bitmask in the valuemask member. The symbols for the value mask bits and **XpmInfo** structure are:

Symbol Name	Symbol Value	Related Members	Comments
<b>XpmComments</b>	(1L<<8)	hints_cmt, colors_cmt, pixels_cmt	
<b>XpmReturnComments</b>	<i>idem</i>	<i>idem</i>	Will be unset in case of memory allocation failure.
<b>XpmColorTable</b>	(1L<<15)	colorTable, ncolors	
<b>XpmReturnColorTable</b>	<i>idem</i>	<i>idem</i>	Will be unset in case of memory allocation failure.
<b>XpmExtensions</b>	(1L<<10)	extensions, nextensions	

Symbol Name	Symbol Value	Related Members	Comments
<b>XpmReturnExtensions</b>	<i>idem</i>	<i>idem</i>	Will be unset in case of memory allocation failure.

**NOTE:** In any case the **XpmInfo** structure valuemask must be set to some valid value, at least zero, otherwise unpredictable errors can occur.

### 3.2.2 Functions to deal with XPM files

To create an **XpmImage** from an **XPM** file, use **XpmReadFileToXpmImage**.

```
int XpmReadFileToXpmImage(filename, image, info)
    char *filename;
    XpmImage *image;
    XpmInfo *info;
```

*filename* Specifies the file name to read from.

*image* Specifies the image structure location.

*info* Specifies the location of a structure to store possible information (or NULL).

The **XpmReadFileToXpmImage** function reads in a file in the **XPM** format. If the file cannot be opened it returns **XpmOpenFailed**. If the file can be opened but does not contain valid **XPM** data, it returns **XpmFileInvalid**. If insufficient working storage is allocated, it returns **XpmNoMemory**. On success it fills in the given **XpmImage** structure and returns **XpmSuccess**.

If the passed **XpmInfo** structure pointer is not **NULL**, **XpmReadFileToXpmImage** looks for the following attributes: **XpmReturnComments** and **XpmReturnExtensions**, and sets possibly the **XpmHotspot** attribute when returning. In any case, if requested data cannot be returned because of insufficient memory storage, **XpmReadFileToXpmImage** will change the valuemask to mention this and will try to continue. So the caller should check on this before accessing requested data.

Note: The valuemask of the passed **XpmInfo** structure must be set to some valid value, at least zero, otherwise unpredictable errors can occur.

In addition on systems which support such features **XpmReadFileToXpmImage** deals with compressed files by forking an **uncompress** or **gzip** process and reading from the piped result. It assumes that the specified file is compressed if the given file name ends by **'.Z'** or **'.gz'**. In case the file name does not end so, **XpmReadFileToXpmImage** first looks for a file of which the name is the given one followed by **'.Z'** or **'.gz'**; then if such a file does not exist, it looks for the given file (assumed as not compressed). And if instead of a file name **NULL** is passed to **XpmReadFileToXpmImage**, it reads from the standard input.

To write out an **XpmImage** to an **XPM** file, use **XpmWriteFileFromXpmImage**

```
int XpmWriteFileFromXpmImage(filename, image, shapeimage, info)
    char *filename;
    XpmImage *image;
```

```

        XpmInfo *info;
filename      Specifies the file name to use.
image        Specifies the image.
info         Specifies the location of a structure to get information from (or NULL).

```

The **XpmWriteFileFromXpmImage** function writes an image out to a file in the **XPM** format. If the file cannot be opened, it returns **XpmOpenFailed**. If insufficient working storage is allocated, it returns **XpmNoMemory**. If no error occurs then it returns **XpmSuccess**.

If the passed **XpmInfo** structure pointer is not **NULL**, **XpmWriteFileFromXpmImage** looks for the following attributes: **XpmComments**, **XpmExtensions**, and **XpmHotspot**, and writes the related information out as well.

In addition on systems which support such features if the given file name ends by **'.Z'** or **'.gz'** it is assumed to be a compressed file. Then, **XpmWriteFileFromXpmImage** writes to a piped **compress** or **gzip** process. And if instead of a file name **NULL** is passed to **XpmWriteFileFromXpmImage**, it writes to the standard output.

### 3.2.3 Functions to deal with XPM data

To create an **XpmImage** from an **XPM** data, use **XpmCreateXpmImageFromData**.

```

int XpmCreateXpmImageFromData(data, image, info)
    char **data;
    XpmImage *image;
    XpmInfo *info;
data      Specifies the location of the data.
image     Specifies the image structure location.
info      Specifies the location of an XpmInfo structure to get and store information (or NULL).

```

**XpmCreateXpmImageFromData** fills in the given **XpmImage** structure from the given data. If the data does not contain valid **XPM** data, it returns **XpmFileInvalid**. If insufficient working storage is allocated, it returns **XpmNoMemory**, on success it returns **XpmSuccess**.

If the passed **XpmInfo** structure pointer is not **NULL**, **XpmCreateXpmImageFromData** looks for the following attributes: **XpmReturnExtensions**, and sets possibly the **XpmHotspot** attribute when returning. In any case, if requested data cannot be returned because of insufficient memory storage, **XpmCreateXpmImageFromData** will change the valuemask to mention this and will try to continue. So the caller should check on this before accessing requested data.

Note: The valuemask of the passed **XpmInfo** structure must be set to some valid value, at least zero, otherwise unpredictable errors can occur.

**XpmCreateDataFromXpmImage** creates an **XPM** data from an **XmImage**.

```

int XpmCreateDataFromXpmImage(data_return, image, info)
    char ***data_return;
    XpmImage *image;

```

```

        XpmInfo *info;
data_return    Returns the data which is created.
image         Specifies the image.
info          Specifies the location of a structure to get information.

```

The **XpmCreateDataFromXpmImage** function writes out the given *image* to a single block malloc'ed data in **XPM** format. If insufficient working storage is allocated, it returns **XpmNoMemory**, and returns **XpmSuccess** on success.

If the passed **XpmInfo** structure pointer is not **NULL**, **XpmCreateDataFromXpmImage** looks for the following attributes: **XpmExtensions**, and **XpmHotspot**, and writes the related information out as well.

It is the caller's responsibility to free the data, using **XpmFree** when finished.

### 3.2.4 Functions to deal with XPM buffers

To create an **XpmImage** from an **XPM** buffer, use **XpmCreateXpmImageFromBuffer**.

```

int XpmCreateXpmImageFromBuffer(buffer, image, info)
    char *buffer;
    XpmImage *image;
    XpmInfo *info;
buffer    Specifies the location of the buffer.
image     Specifies the image structure location.
info      Specifies the location of a structure to store possible information (or NULL).

```

The **XpmCreateXpmImageFromBuffer** reads the given *buffer* to fill in the given **XpmImage** structure. If the buffer does not contain valid **XPM** data, it returns **XpmFileInvalid**. If insufficient working storage is allocated, it returns **XpmNoMemory**, and returns **XpmSuccess** on success.

If the passed **XpmInfo** structure pointer is not **NULL**, **XpmCreateXpmImageFromBuffer** looks for the following attributes: **XpmReturnComments** and **XpmReturnExtensions**, and sets possibly the **XpmHotspot** attribute when returning. In any case, if requested data cannot be returned because of insufficient memory storage, **XpmCreateXpmImageFromBuffer** will change the valuemask to mention this and will try to continue. So the caller should check on this before accessing requested data.

Note: The valuemask of the passed **XpmInfo** structure must be set to some valid value, at least zero, otherwise unpredictable errors can occur.

To create an **XPM** buffer from an **XpmImage**, use **XpmCreateBufferFromXpmImage**.

```

int XpmCreateBufferFromXpmImage(buffer_return, image, info)
    char **buffer_return;
    XpmImage *image;
    XpmInfo *info;
buffer_return  Returns the buffer which is created.

```

*image*                      Specifies the image.  
*info*                        Specifies the location of a structure to get possible information (or NULL).

The **XpmCreateBufferFromXpmImage** writes out the given *image* to a single block malloc'ed buffer in **XPM** format. If insufficient working storage is allocated, it returns **XpmNoMemory**, and returns **XpmSuccess** on success.

If the passed **XpmInfo** structure pointer is not **NULL**, **XpmCreateBufferFromXpmImage** looks for the following attributes: **XpmComments**, **XpmExtensions**, and **XpmHotspot**, and writes the related information out as well.

The caller should free the buffer using **XpmFree** when finished.

### 3.2.5 Functions to deal with X images

To create an **XImage** from an **XpmImage**, use **XpmCreateImageFromXpmImage**.

```
int XpmCreateImageFromXpmImage(display, image, image_return, shapeimage_return, attributes)
    Display *display;
    XpmImage *image;
    XImage *image_return;
    XImage *shapeimage_return;
    XpmAttributes *attributes;
```

*display*                      Specifies the connection to the X server.  
*image*                        Specifies the **XpmImage**.  
*image\_return*                Returns the image which is created.  
*shapeimage\_return*        Returns the shape mask image which is created if any.  
*attributes*                  Specifies the location of a structure containing information (or NULL).

From the given **XpmImage** and **XpmAttributes** if not **NULL**, **XpmCreateImageFromXpmImage** allocates colors and creates X images following the same mechanism as **XpmReadFileToImage** (page 15).

When finished the caller must free the images using **XDestroyImage**, the colors using **XFreeColors**, and possibly the data returned into the **XpmAttributes** using **XpmFreeAttributes** (page 23).

To create an **XpmImage** from an **XImage**, use **XpmCreateXpmImageFromImage**.

```
int XpmCreateXpmImageFromImage(display, image, shapeimage, xpmimage, attributes)
    Display *display;
    XImage *image;
    XImage *shapeimage;
    XpmImage *xpmimage
    XpmAttributes *attributes;
```

*display*                      Specifies the connection to the X server.  
*image*                        Specifies the image which is created.  
*shapeimage*                Specifies the shape mask image which is created if any.

*xpmimage* Specifies the location of an **XpmImage** structure.  
*attributes* Specifies the location of a structure containing information (or NULL).

From the given X images and **XpmAttributes** if not **NULL**, **XpmCreateXpmImageFromImage** creates an **XpmImage** following the same mechanism as **XpmWriteFileFromImage**.

### 3.2.6 Functions to deal with X pixmaps

To create a **Pixmap** with its possible related shapemask from an **XpmImage**, use **XpmCreatePixmapFromXpmImage**.

```
int XpmCreatePixmapFromXpmImage(display, d, image, pixmap_return, shapemask_return, attributes)
```

```
    Display *display;  
    Drawable d;  
    XpmImage *image;  
    Pixmap *pixmap_return;  
    Pixmap *shapemask_return;  
    XpmAttributes *attributes;
```

*display* Specifies the connection to the X server.  
*d* Specifies which screen the pixmap is created on.  
*image* Specifies the **XpmImage**.  
*pixmap\_return* Returns the pixmap which is created.  
*shapemask\_return* Returns the shape mask which is created if any.  
*attributes* Specifies the location of a structure to get and store information (or NULL).

**XpmCreatePixmapFromXpmImage** creates X images calling **XpmCreateImageFromXpmImage** (page 28) with the given **XpmImage** and **XpmAttributes**, then it creates the related pixmaps which are returned to *pixmap\_return* and *shapemask\_return* using **XPutImage**. Finally it destroys the X images with **XDestroyImage**.

When finished the caller must free the pixmaps using **XFreePixmap**, the colors using **XFreeColors**, and possibly the data returned into the **XpmAttributes** using **XpmFreeAttributes**.

To create an **XpmImage** from a **Pixmap**, use **XpmCreateXpmImageFromPixmap**.

```
int XpmCreateXpmImageFromPixmap(display, pixmap, shapemask, xpmimage, attributes)
```

```
    Display *display;  
    Pixmap *pixmap;  
    Pixmap *shapemask;  
    XpmImage *xpmimage  
    XpmAttributes *attributes;
```

*display* Specifies the connection to the X server.  
*pixmap* Specifies the pixmap.  
*shapemask* Specifies the shape mask pixmap.  
*xpmimage* Specifies the location of an **XpmImage** structure.

*attributes* Specifies the location of a structure containing information (or NULL).

From the given pixmaps and **XpmAttributes** if not **NULL**, **XpmCreateXpmImageFromPixmap** gets the related X images by calling **XGetImage**, then it gives them to **XpmCreateXpmImageFromImage** (page 28) to create an **XpmImage** which is returned to *xpmimage*. Finally it destroys the created X images using **XDestroyImage**.

### 3.2.7 Miscellaneous functions

To free possible data stored into an **XpmImage** structure use **XpmFreeXpmImage**.

```
int XpmFreeXpmImage(image)
    XpmImage *image;
```

*image* Specifies the structure to free.

The **XpmFreeXpmImage** frees the structure members which are not **NULL**, but not the structure itself.

To free possible data stored into an **XpmInfo** structure use **XpmFreeXpmInfo**.

```
int XpmFreeXpmInfo(info)
    XpmInfo *info;
```

*info* Specifies the structure to free.

The **XpmFreeXpmInfo** frees the structure members which are not **NULL**, but not the structure itself.
